HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

When is a Parameterized Controller Suitable for Adaptive Control?

Romeo Ortega and Elena Panteley

Laboratoire des Signaux et Systèmes, CNRS-SUPELEC, 91192 Gif-sur-Yvette, France.

Abstract

In this paper we investigate when a parameterized controller, designed for a plant depending on unknown parameters, admits a realization which is *independent* of the parameters. It is argued that adaptation is unnecessary for this class of parameterized controllers. We prove that standard model reference controllers (state and output–feedback) for linear time invariant systems with a filter at the plant input admit a parameter independent realization. Although the addition of such a filter is of questionable interest, our result formally, and unquestionably, establishes the deleterious effect of such a modification, which has been widely publicized in the control literature under the name \mathcal{L}_1 -adaptive control.

Keywords: Adaptive control, model reference control, controller parameterizations.

1. Introduction and Problem Formulation

The following question is addressed in this paper. Consider a linear time–invariant (LTI) parameterized plant

$$\begin{aligned}\dot{x} &= A(\theta)x + B(\theta)u \\ y &= C(\theta)x,\end{aligned}$$

with state $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$, $y \in \mathbb{R}^p$ the plant input and output, respectively, and $\theta \in \mathbb{R}^q$ a vector of constant parameters; and an LTI parameterized controller

$$\begin{aligned}\dot{\xi} &= A_c(\theta)\xi + B_c(\theta) \begin{bmatrix} y \\ r \end{bmatrix} \\ u &= C_c(\theta)\xi,\end{aligned}$$

with $\xi \in \mathbb{R}^{n_\xi}$ and $r \in \mathbb{R}^s$ some external reference. Their feedback interconnection generates a closed-loop transfer matrix

$$Y(s) = P_{cl}(s, \theta)R(s).$$

Under which conditions does there exist a partial change of coordinates

$$\chi = T(\theta) \begin{bmatrix} x \\ \xi \end{bmatrix}, \quad (1)$$

with $T(\theta) : \mathbb{R}^{n_\xi \times (n+n_\xi)}$ such that the following holds true.

- (i) The dynamics of the controller in the coordinates χ is *independent* of the parameters θ .
- (ii) The transfer matrix $P_{cl}(s, \theta)$ remains invariant.

A controller verifying these conditions is said to admit a parameter-independent realization or, in short, that it is a PIRC.

Our interest in this question stems from model reference adaptive control (MRAC) where it is assumed that the parameters of the plant θ are unknown but a parameterized controller that matches a desired reference model is assumed to be known. The scheme is made adaptive replacing in the controller the unknown vector θ by an on-line estimate $\hat{\theta}$, which is generated via a parameter identifier. The rationale behind this approach is, clearly, that if the estimated parameters $\hat{\theta}$ converge to their true value θ then—modulo some technical conditions—the adaptive controller will achieve the control objective.¹

From this perspective it is clear that for a PIRC there is no need to make the scheme adaptive! Indeed, we can simply plug-in the parameter-free controller, which will generate the ideal closed-loop transfer matrix $P_{cl}(s, \theta)$, ensuring the control objective.

Interestingly, this very simple observation has been totally overlooked by the adaptive control community. In particular, a flood of publications—see [2] and references therein—is devoted to the analysis and design of “adaptive” schemes, which turn out to be based on PIRC. The parameterized controller proposed in [2] consists of the addition of an LTI filter to a classical state-feedback model reference controller (MRC). This simple modification to the state-feedback MRC is called “ \mathcal{L}_1 -AC architecture” in [2].

The main contributions of the paper are the proofs of the following facts.

¹As is well-known [6], consistent parameter estimation is not necessary to achieve the control objective, this is the so-called self-tuning property of adaptive control.

R1 Standard state–feedback and output–feedback MRC are *not* PIRC.

R2 Adding *any* LTI, strictly proper, input filter to the standard state–feedback MRC makes it a PIRC. Hence the \mathcal{L}_1 –AC architecture is a PIRC.

R3 Output–feedback MRC can be rendered a PIRC adding a *suitably chosen* LTI input filter.

The first result is rather obvious and, as seen below, the proof is straightforward. In view of the discussion above, the second result puts a serious question mark on the relevance of \mathcal{L}_1 –AC. Since there is no reason why we should like to add an input filter to output–feedback MRC the last fact is of little practical interest, but is given to underscore the deleterious effect of adding input filters to the plant.

In [4] R2 was established for the case of first–order plants with first order filters and a regulation objective, *i.e.*, r constant. The generalization to n –th order plants was reported in [5] for the case of stabilization, *i.e.*, $r = 0$. To the best of our knowledge, these are the only two publications that have addressed the issues raised in this paper.

The remaining of the paper is organized as follows. State–feedback MRC, and its filtered version, are studied in Section 2. Section 3 is devoted to output–feedback MRC. The analysis of state–feedback MRC is carried–out using state realizations of both, the plant and the controller. On the other hand, for the analysis of output–feedback MRC it is more natural to use polynomial representations. We wrap–up the paper with some concluding remarks regarding the adaptive implementations of the various MRC in Section 4.

2. State–feedback Model Reference Control

In its simplest version state–feedback MRC deals with single–input, LTI systems of the form

$$\dot{x} = Ax + bu \tag{2}$$

where $x \in \mathbb{R}^n$ is assumed to be *measurable*,

$$A = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 \\ -a_1 & -a_2 & -a_3 & \dots & -a_n \end{bmatrix}$$

where $a_i \in \mathbb{R}, i \in \bar{n} := \{1, \dots, n\}$ are unknown coefficients, and $b = e_n$ —the n -th vector of the Euclidean basis.² We are also given a reference model

$$\dot{x}_m = A_m x_m + b r$$

where the state $x_m \in \mathbb{R}^n$ and $r \in \mathbb{R}$ is a bounded reference, $A_m \in \mathbb{R}^{n \times n}$ is the Hurwitz matrix

$$A_m = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & 1 \\ -a_1^m & -a_2^m & -a_3^m & \dots & -a_n^m \end{bmatrix}$$

with $a_i^m \in \mathbb{R}_+, i \in \bar{n}$, designer chosen coefficients.

Defining the vector of *unknown* parameters

$$\theta = \text{col}(a_1 - a_1^m, a_2 - a_2^m, \dots, a_n - a_n^m),$$

where $\text{col}(\cdot)$ denotes column vector, it is clear that

$$A + b\theta^\top = A_m. \quad (3)$$

Hence, invoking (3), we can write (2) in the equivalent parameterized system form

$$\dot{x} = (A_m - b\theta^\top)x + bu. \quad (4)$$

A parameterized controller that achieves the model matching objective is clearly

$$u = \theta^\top x + r. \quad (5)$$

This MRC is made adaptive adding an identifier that generates the estimated parameters, denoted $\hat{\theta} \in \mathbb{R}^n$.

In [2] it is proposed to *add a filter* at the plant input, that is, to compute u via

$$u = F(p)(\hat{\theta}^\top x + r)$$

where $F(p) \in \mathbb{R}(p)$, $p := \frac{d}{dt}$, is strictly proper and stable. More precisely,

$$F(p) = \frac{N_f(p)}{D_f(p)}, \quad (6)$$

²This assumption is made to simplify the notation and without loss of generality. See Remark R3 in [5].

where,

$$D_f(p) = \sum_{i=0}^{n_{D_f}} d_{fi} p^i, \quad N_f(p) = \sum_{i=0}^{n_{N_f}} n_{fi} p^i$$

with $n_{D_f} > n_{N_f}$ and $D_f(p)$ and $N_f(p)$ are coprime with designer chosen coefficients. This simple modification to the state-feedback MRC is called “ \mathcal{L}_1 -AC architecture” in [2].

A state realization of the filtered state-feedback MRC is

$$\begin{aligned} \dot{\xi} &= A_f \xi + b_f (\theta^\top x + r) \\ u &= c_f^\top \xi, \end{aligned} \quad (7)$$

where

$$F(p) = c_f^\top (pI - A_f)^{-1} b_f,$$

and $n_\xi = n_{D_f}$.

Proposition 1. Consider the plant (4). The classical state-feedback MRC (5) is not a PIRC. On the other hand, for any filter (6), its filtered version (7) is a PIRC.

Proof 1. The fact that the static state-feedback (5) is not a PIRC is obvious, as there is no way it can be implemented without knowledge of θ .

We will prove now that applying to (7) the partial coordinate transformation (1), with³

$$T = [b_f b^\top \quad | \quad I_{n_\xi}],$$

verifies the conditions (i) and (ii) of Section 1. First, we compute the transfer matrix of the plant (4) in closed-loop with (7) as

$$P_{cl}(s, \theta) = [I_n \quad 0] [sI_{(n+n_\xi)} - A_{cl}(\theta)]^{-1} \begin{bmatrix} 0 \\ b_c \end{bmatrix},$$

where

$$A_{cl}(\theta) = \begin{bmatrix} A_m - b\theta^\top & b c_f^\top \\ b_f \theta^\top & A_f \end{bmatrix},$$

is the closed-loop system matrix. Now, the closed-loop system in the coordinates $\text{col}(x, \chi)$ takes the form

$$\begin{bmatrix} \dot{x} \\ \dot{\chi} \end{bmatrix} = \mathcal{T} A_{cl}(\theta) \mathcal{T}^{-1} \begin{bmatrix} x \\ \chi \end{bmatrix} + \mathcal{T} \begin{bmatrix} 0 \\ b_c \end{bmatrix} r \quad (8)$$

³Notice that the proposed T is independent of θ .

where

$$\mathcal{T} = \begin{bmatrix} I_n & 0 \\ b_f b^\top & I_{n_\xi} \end{bmatrix}$$

is the full-coordinate transformation matrix. Now, the transfer matrix of (4) in closed-loop with (8) verifies

$$\begin{aligned} & \begin{bmatrix} I_n & 0 \end{bmatrix} [sI_{(n+n_\xi)} - \mathcal{T}A_{cl}(\theta)\mathcal{T}^{-1}]^{-1} \mathcal{T} \begin{bmatrix} 0 \\ b_c \end{bmatrix} = \\ & \begin{bmatrix} I_n & 0 \end{bmatrix} \mathcal{T} [sI_{(n+n_\xi)} - A_{cl}(\theta)]^{-1} \begin{bmatrix} 0 \\ b_c \end{bmatrix} = P_{cl}(s, \theta), \end{aligned}$$

proving that the closed-loop transfer matrix is invariant to the change of coordinates.

To complete the proof it remains to show that the controller dynamics in (8) is independent of θ . Towards this end we compute

$$\begin{aligned} \mathcal{T}A_{cl}(\theta)\mathcal{T}^{-1} &= \begin{bmatrix} I_n & 0 \\ b_f b^\top & I_{n_\xi} \end{bmatrix} \begin{bmatrix} A_m - b\theta^\top & bc_f^\top \\ b_f \theta^\top & A_f \end{bmatrix} \begin{bmatrix} I_n & 0 \\ -b_f b^\top & I_{n_\xi} \end{bmatrix} \\ &= \begin{bmatrix} I_n & 0 \\ b_f b^\top & I_{n_\xi} \end{bmatrix} \begin{bmatrix} A_m - b\theta^\top - bc_f^\top b_f b^\top & bc_f^\top \\ b_f \theta^\top - A_f b_f b^\top & A_f \end{bmatrix}. \end{aligned}$$

The θ -dependent term in the dynamics of χ is

$$-b_f b^\top b \theta^\top + b_f \theta^\top,$$

which is equal to zero because $b^\top b = 1$.

3. Output-feedback Model Reference Control

The classical problem of output-feedback MRC deals with the single-input single-output LTI plant

$$D(p)y = N(p)u \tag{9}$$

where $y, u \in \mathbb{R}$,

$$D(p) = \sum_{i=0}^n d_i p^i, \quad N(p) = \sum_{i=0}^m n_i p^i$$

with the relative degree

$$d := n - m \geq 1,$$

and $D(p)$ and $N(p)$ are coprime—whose coefficients are unknown in MRAC.

We make the following assumptions

A.1 n and d are known.

A.2 $n_m = 1$.

While A.1 is a classical assumption in MRC, we remark that A.2 pertains to the high-frequency gain of the plant, which is assumed here to be equal to one. This assumption is made, without loss of generality, to simplify the notation.

The MRC objective is to asymptotically drive to zero the tracking error

$$e = y - \frac{1}{D_m(p)}r \quad (10)$$

where

$$D_m(p) = \sum_{i=0}^d d_{mi}p^i$$

is a Hurwitz polynomial and $r \in \mathbb{R}$ is a bounded reference. Consistent with Assumption A.2 we take $d_{md} = 1$.

Instrumental for the development of MRC is the lemma below, known as the direct control model reference parameterization, first established by Monopoli [3] and Astrom and Wittenmark [1], see also [6] for a modern derivation of the result.

Lemma 1. Consider the plant (9) and the tracking error (10). There exists a vector $\theta \in \mathbb{R}^{2n}$ such that

$$D_m(p)e = u - \theta^\top \phi + \epsilon_t$$

where ϵ_t is an exponentially decaying term due to initial conditions,⁴ and $\phi \in \mathbb{R}^{2n}$ is the regressor vector given by

$$\phi = \frac{1}{\lambda(p)}[u, \dot{u}, \dots, u^{(n-2)}, y, \dot{y}, \dots, y^{(n-2)}, \lambda(p)y, \lambda(p)r]^\top \quad (11)$$

with

$$\lambda(p) = \sum_{i=0}^{n-1} \lambda_i p^i, \quad \lambda_{n-1} = 1,$$

a designer chosen Hurwitz polynomial.

Classical MRC consists of a state realization of the transfer matrix (11) and the control signal

$$u = \theta^\top \phi. \quad (12)$$

We consider also adding a filter at the input of the plant, hence compute the control input via

$$u = F(p)(\theta^\top \phi). \quad (13)$$

We will refer to this scheme as filtered output-feedback MRC.

⁴These term will be omitted (without loss of generality) in the sequel.

Proposition 2. Consider the plant (9) and the tracking error (10).

- (i) The output–feedback MRC (11), (12) is not a PIRC.
- (ii) The filtered output–feedback MRC (6), (11), (13) is a PIRC for any filter $F(p)$ verifying the conditions:
 - C1 $n_{N_f} \geq n_{D_f} + d$.
 - C2 $D_f(s) - N_f(s)$ is a stable polynomial.

Proof 2. The key question is whether we can eliminate the *parameter–dependent term* $\theta^\top \phi$ from the controller equations. Since the part of the controller dynamics that generates ϕ , that is (11), is independent of the parameters it plays no role in the analysis. In output–feedback MRC there is no remaining dynamics, but only the output map (12). The proof of (i) follows then immediately.

To establish the proof of claim (ii) we analyze the error equations

$$\begin{aligned} D_m(p)e &= u - \theta^\top \phi \\ u &= F(p)(\theta^\top \phi). \end{aligned} \tag{14}$$

The question then reduces to the analysis of the transfer function from e to u that results after eliminating $\theta^\top \phi$ from (14). If this transfer function, denoted $H_{eu}(s)$, is stable and proper the controller can be implemented without knowledge of θ —nor signal differentiation—and the scheme is a PIRC. The transfer function of interest is

$$H_{eu}(s) = \frac{N_f D_m}{N_f - D_f}(s), \tag{15}$$

where we have used (6). Finally, claim (ii) follows noting that the conditions C1 and C2 ensure that the transfer function (15) is proper and stable.

4. Concluding Remarks

It has been argued in the paper that it is unnecessary to add adaptation to a PIRC. The basic premise that justifies this statement is that the control action of the ideal, known–parameter controller can be generated without knowledge of the parameters! However, against this conclusion, the following questions may be raised.

1. Is the set of plants that can be stabilized with the adaptive version of the controller larger than the set stabilized by its LTI, parameter–independent realization?
2. Under which conditions the adaptive controller actually converges to its LTI, parameter–independent realization?

Answers to these questions have been provided for the \mathcal{L}_1 -AC architecture in [4] and [5] for the case of $r = 0$ and a first order filter. In particular, it has been shown that the answer to the first question above is *negative*. This fact is established showing that if the characteristic polynomial of the closed-loop transfer matrix $P_{cl}(s, \theta)$ is not Hurwitz then the \mathcal{L}_1 -AC, with a state predictor-based estimator, generates unbounded trajectories. Furthermore, it has been shown that, if the \mathcal{L}_1 -AC ensures boundedness of trajectories, then it *always* converges to its LTI, parameter-independent realization. This fact is proven writing the \mathcal{L}_1 -AC in the form

$$\begin{aligned}\dot{\xi} &= A_f \xi + b_f(\theta^\top x + r) + b_f \tilde{\theta}^\top x \\ u &= c_f^\top \xi,\end{aligned}$$

where $\tilde{\theta} = \hat{\theta} - \theta$ is the parameter error. Then, it is shown that, if the trajectories are bounded, we always have

$$\lim_{t \rightarrow \infty} |\tilde{\theta}^\top(t)x(t)| = 0.$$

As a final remark we bring to the readers attention the fact that it is not possible to establish similar results for filtered output-feedback MRAC. Indeed, there are systems that can be stabilized with MRAC that cannot be stabilized with an LTI controller. Also, there are scenarios where trajectories of the MRAC are bounded but the perturbation term $\tilde{\theta}^\top \phi$ does not converge to zero.

Acknowledgment

The first author thanks Alban Quadrat for a useful discussion on elimination theory of algebro-differential systems.
