Abstract

Most data-driven diagnosis methods that are designed to detect faults, rely on measuring the mean and variation shifts. However, for incipient fault detection, these statistical criteria are slightly varying and are difficult to be accurately evaluated to reach good performances. Indeed, such faults are more likely to induce slight changes on the probability distribution rather than particular parametric changes. Therefore, the Jensen-Shannon Divergence (JSD), characterized by high sensitivity in measuring minor changes between probability distributions, is proposed in this paper. Its efficiency for detection and estimation is theoretically studied and validated by simulated data considering an auto-regressive (AR) system designing a multivariate data-driven process. The superior detection performances are demonstrated and compared with other more traditional statistical tests such as the Hotelling's T^2 and the Squared Prediction Error (SPE) in the Principal Component Analysis (PCA) framework. Minor crack detection based on eddy-currents testing (ECT) experimental data are evaluated to highlight the performances of our proposal. The results show that JSD can detect minor cracks ($0.01mm^2$ to $0.04mm^2$) which were not possible when using the baseline impedance signal measurement. For the fault severity estimation, the accuracy of the theoretical model derived for Gaussian distributed signals is shown with an AR system. The maximum relative estimation error obtained in the worst faults severity conditions is smaller than 2.75% when the Signal to Noise Ratio (SNR) is larger than 25dB and smaller than 2.15%

when the Fault to Noise Ratio (FNR) is larger than -21dB . Application for the fault severity estimation on the ECT data validates the effectiveness of this fault estimation model.

Keywords: Incipient fault, Fault detection and estimation, Jensen Shannon Divergence, Data-driven process, Principal Component Analysis.

1. Introduction

Incipient fault diagnosis plays a key role in the automation of inspection procedure and minimization of maintenance activities and costs [1, 2]. An incipient fault is mainly characterized by its slowly developing behavior and its barely noticeable effects [3, 4, 5]. Besides this type of defect is difficult to detect, it is dangerous for a system if its severity is underestimated. The early detection of the incipient fault can help to schedule preventive maintenance and prevent more serious failures [6]. For quantifying the fault severity, the estimation of the incipient fault is necessary.

The existing methods of fault detection and estimation can be generally classified as model-based and data-driven-based solutions [7, 8]. The model-based approach is related to the theoretical derivation of the system behavior. Its performances widely depend on the accuracy of the mathematical model which is degraded due to uncertainties, evolution of operating conditions, environmental changes, etc [9]. In contrast to the model-based approach, the process-history-based methods are based on the availability of a sufficient amount of historical process data to perfectly describe the process behavior using well-chosen descriptive features [5, 10, 11]. Basically, techniques that are often used for data-driven approaches are linked to the evaluation of statistical moments with order 1 to 4 (sample mean, variance, skewness, and kurtosis), Hotelling's T^2 , squared prediction error (SPE), Cumulative Sum (CUSUM), ... [7, 12, 13]. These methods are efficient in measuring the parameter change of the data but are not accurate enough for incipient fault detection. These later seem more likely to cause a change of the probability distribution rather than obvious parameter change [14]. Particular techniques based on specific distance measures have then to be considered to detect such faults [15, 16]. Jensen-Shannon divergence (JSD) is a particular symmetrical operation of Kullback-Leibler information. It is a well-known tool for detecting the dissimilarities between probability distributions [17, 18]. It has been used in many domains such as image processing, text categoriza-

tion, and subject recognition. Its superior change detection capability has been well observed in [19, 20, 21, 22] for particular contexts. Nevertheless, to the best of our knowledge, the efficiency of this technique has never been considered in the particular working conditions of incipient fault that can be masked by the noise environment.

In this paper, JSD is proposed to detect incipient fault for different noise levels in a multivariate data-driven process. Firstly, a theoretical model is developed to prove the detection efficiency of the technique. As a preprocessing and feature extraction method, Principal Component Analysis (PCA), which effectiveness in fault detection and estimation is well known [23, 24, 25, 26], is used to reduce the dimensionality of the processed variables [27] and extract the most informative feature. Meanwhile, the maximum information is kept in this new feature space and the probability density functions of the system in healthy and faulty conditions can be derived. The detection performances are evaluated considering JSD but also typical statistics algorithms (Hotelling's T^2 and SPE) with well-proved detection capabilities in process health monitoring [7, 26, 28, 29]. These performances are shown using a simulated AR process and compared to each other. To experimentally validate this detection step, minor material cracks based on Eddy Current Testing (ECT) data are considered.

The existence of material crack is harmful to the safety of an industrial system particularly in the transportation industry (planes, rockets, trains, vehicles, ...). In order to detect these cracks, a regular inspection of the system is required during all the production and maintenance process. Non-destructive evaluation (NDE) technique can be used to test the inside defects of materials and structures without affecting its operating conditions [30, 31]. For conductive metallic materials, Eddy current based techniques such as Pulsed Eddy current (PEC) or Eddy Current Testing (ECT) are the main typical ones that are most often used as non-destructive testing methods for crack detection [32, 33, 34]. They are based on the principle that the inhomogeneity due to the defect will cause measurement shifts compared to the initial healthy conditions. To be applied in high-dimensional data conditions, fault feature extraction methods such as Principal Component Analysis (PCA) [35], Independent Component Analysis (ICA) [36], or Fisher Discriminant Analysis (FDA) [37] have been applied for the cracks diagnosis. Most of these works are focused on large cracks detection. This implies a significant visible signature due to the presence of the fault in the eddy current signals with a very low influence of the environmental noise. However,

in the case of minor cracks, which can be considered as incipient faults, the measurement variation due to the fault is weak. The fault signature compared to the roughness leads to a measured signal that does not clearly indicate the presence of the crack. Particularly, the measurement accuracy is largely affected by external measurement environment, the roughness of the surface, internal and sensor noise sensitivity, \dots [33, 38]. Thus, the detection and diagnosis for these incipient cracks in a high noise level are more tricky. In this paper, Jensen-Shannon divergence is proposed and used for incipient cracks detection in a high noise level based on the experimental ECT data. With our proposal, we show that it is possible to detect smaller cracks than those that have already been evaluated in the literature to the best of our knowledge.

The second aim of this paper concerns the fault severity estimation. Based on the JSD, we propose a theoretical model derived for Gaussian distributed data. The efficiency of this estimation process is validated using the simulated AR process and the experimental ECT data. As the incipient faults lead to very low fault severities they can be masked by the environmental noise of the process. Then, the accuracy of our estimation results is discussed for several operating conditions corresponding to different Signal to Noise Ratio (SNR) and Fault to Noise Ratio (FNR). With our proposal this estimation is, to the best of our knowledge, the first that have been obtained for those crack size in noisy environment. Offering a slight overestimation of the fault severity and a very low error rate, this proposal allows to have a valuable safety margin in the health monitoring process.

This paper is organized as follows. The detailed incipient fault diagnosis process and main notations are described in Section 2. Section 3 and 4 respectively presents the derived incipient fault detection and estimation models with the evaluation of their performances and their application to ECT data. The last section 5 concludes the paper.

2. Incipient Fault Diagnosis Process

2.1. Main notations and fault model

Let's first define the main notations used throughout the paper:

- $\mathbf{X}_{[N \times m]} = (\mathbf{x}_1, \dots, \mathbf{x}_j, \dots, \mathbf{x}_k, \dots, \mathbf{x}_m)$ represents original data matrix, in which m is the number of variables and N is the sample size. \mathbf{x}_k is the k^{th} vector such as $\mathbf{x}_k = [x_{1k}, \dots, x_{ik}, \dots, x_{Nk}]^T$, where $i = [1, \dots, N]$

- 104 is the sample number. x_{ik} is then the i^{th} data sample of the k^{th} vari-
 105 able. \mathbf{x}_j denotes the variable affected by the fault occurred within the
 106 sampling interval $[b, N]$, (\top) is the transpose matrix operator.
- 107 • \mathbf{S} is the sample data covariance matrix,
 - 108 • $\bar{\mathbf{X}}_{[N \times m]}$ is the centered and normalized matrix.
 - 109 • l corresponds to the dimension of the principal subspace, leading to
 110 the l first principal components. The $m - l$ remaining ones give the
 111 dimension of the residual subspace.
 - 112 • $\mathbf{P}_{[m \times m]}$ is the eigenvectors matrix (also denoted the loadings matrix) of
 113 \mathbf{S} associated to the eigenvalues $\mathbf{\Lambda}$, such as $diag(\mathbf{\Lambda}) = [\lambda_1, \dots, \lambda_k, \dots, \lambda_m]$.
 - 114 • $D_{JS}(\cdot)$ denotes Jensen-Shannon Divergence, $D_{JS_{An}}$ is the approximated
 115 theoretical equation of JSD derived for Gaussian distributed data.
 - 116 • l is the crack length, and d is crack depth.
 - 117 • pdf denotes the probability density function.
 - 118 • P_{FA} refers to the probability of false alarm, and P_D is the probability
 119 of detection.
 - 120 • The mark $(*)$ refers to faultless and noise-free data, mark (\sim) mentions
 121 the faulty and noise-free data function, (\smile) marks the faulty and noisy
 122 data, (\wedge) marks the estimated function.

123 For our work, the fault model is based on the assumption that the fault
 124 severity is constant. The fault occurs at instant time b on the j^{th} variable,
 125 whereas its last $(N - b)$ observations are affected by the fault.

126 A white Gaussian signal $\mathbf{v}_k \sim \mathcal{N}(0, \sigma_v^2)$ is used to simulate the noise in
 127 the environment. The noise matrix is then $\mathbf{V}_{[N \times m]} = (\mathbf{v}_1, \dots, \mathbf{v}_k, \dots, \mathbf{v}_m)$,
 128 where $\mathbf{v}_j = [v_{1j}, \dots, v_{ij}, \dots, v_{Nj}]^\top$ is the noise vector of N samples that
 129 affecting the j^{th} variable. Thus, the faulty variable \mathbf{x}_j can be written as:

$$\mathbf{x}_j = \mathbf{x}_j^* + \mathbf{F}_j + \mathbf{v}_j \quad (1)$$

130 where \mathbf{F}_j is the fault and its structure is denoted as:

$$\mathbf{F}_j = g \times [0 \dots 0 \dots x_{bj}^* \dots x_{Nj}^*]^\top \quad (2)$$

131 where g is the fault severity amplitude.

2.2. Diagnosis process

The diagnosis procedure proposed for fault detection and estimation of a multivariate data-driven process in the Principal Component Analysis framework is shown in Fig.1.

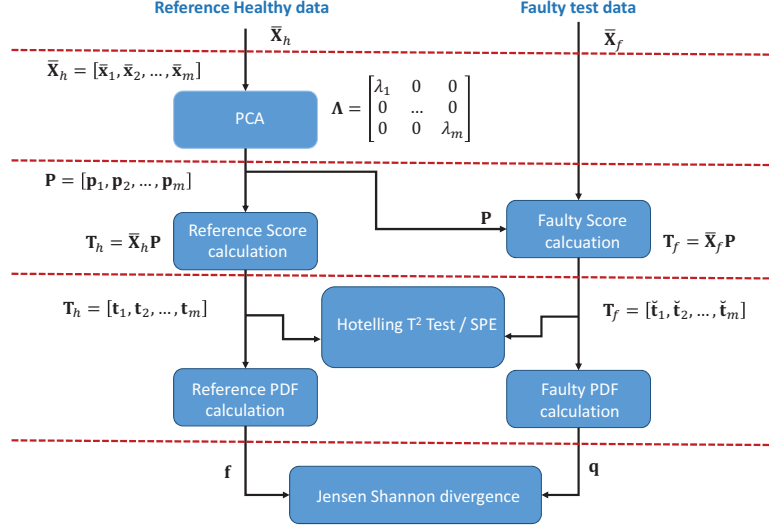

Figure 1: Proposed fault diagnosis procedure

The main operations of the diagnosis procedure based on JSD, T^2 and SPE are described in the following items:

- The input data of PCA are first preprocessed and mean-centered. The PCA model is then established based on the reference healthy data. So, the eigenvalues and eigenvectors matrices Λ and P are derived respectively.
- The reference score T_h and the faulty score T_f are obtained from the data matrices using the same eigenvector matrix P .
- The probability densities of each latent score of T_h and each latent score of T_f are estimated using a normal kernel estimator.
- The diagnosis using Jensen-Shannon divergence is based on the pdfs of the first principal component scores of T_h and T_f . The diagnosis using Hotelling's T^2 is based on the principal component scores in the principal subspace, and SPE uses the scores of the residual one.

150 2.3. Materials and methods for our proposal

151 2.3.1. Principal Component Analysis

152 In fault detection process for multivariate systems, Principal Component
153 Analysis (PCA) has been widely used as preprocessing (filtering and dimen-
154 sion reduction) or feature extraction (fault feature, component selection, ...) [24, 25, 26, 29, 30, 39]. In our study, PCA is used for dimension reduction
155 and component selection. Its major steps can be summarized as follows.

156 First, the covariance matrix \mathbf{S} of sample data can be defined as:

$$157 \quad \mathbf{S} = \frac{1}{N-1} \bar{\mathbf{X}}^\top \bar{\mathbf{X}} \quad (3)$$

158 where $\bar{\mathbf{X}}_{[N \times m]}$ is the centered and normalized matrix. Each vector of this
159 matrix $\bar{\mathbf{X}}$ is written as:

$$\bar{\mathbf{x}}_k = \frac{\mathbf{x}_k - \mu_k}{\sqrt{\sigma_k^2}} \quad (4)$$

160 where μ_k and σ_k^2 are the mean and the variance for the k^{th} variable ($k =$
161 $1, 2, \dots, m$). The Principal Component scores matrix $\mathbf{T}_{[N \times m]}$ can be deter-
162 mined using the linear transformation:

$$\mathbf{T}_{[N \times m]} = \bar{\mathbf{X}}_{[N \times m]} \mathbf{P}_{[m \times m]} = (\mathbf{t}_1, \dots, \mathbf{t}_k \dots, \mathbf{t}_m) \quad (5)$$

163 where $\mathbf{P} = (\mathbf{p}_1, \dots, \mathbf{p}_l, \dots, \mathbf{p}_m)$ is the eigenvectors matrix of \mathbf{S} associated to
164 the corresponding eigenvalues $\lambda_1, \dots, \lambda_l, \dots, \lambda_m$.

165 The principal subspace is defined by the first l principal components, and
166 the residual one is determined by the remaining $(m-l)$ components. In our
167 paper, the number of principal components (PCs) l is obtained calculating
168 the Cumulative Percent of Variance (CPV) [39, 40].

$$\text{CPV}(l) = \frac{\sum_1^l \lambda_k}{\sum_1^m \lambda_k} \geq 90\% \quad (6)$$

169 The number of PCs cumulatively contributing to more than 90 percent
170 data variance will lead us to the principal subspace.

171 2.3.2. Hotelling's T^2 and SPE

172 Typical detection indices are distance-based, aiming at evaluating how
173 much a new observation is away from each of the subspaces. The Hotelling's
174 T^2 is the typical statistic test based on the principal subspace, and SPE is the

175 typical statistic criterion based on the residual subspace. The observations
 176 of T^2 instant i is:

$$T^2 = \sum_{k=1}^l \frac{t_{ik}^2}{\lambda_k} \quad (7)$$

177 The threshold for T^2 can be approximated by:

$$T_{l,\alpha}^2 = \frac{l(N^2 - 1)}{N(N - l)} \mathcal{F}_{l,N-l,\alpha} \quad (8)$$

178 where $\mathcal{F}_{l,N-l,\alpha}$ is the Fisher distribution with two degrees of freedom, l and
 179 $N - l$.

180 The observations of SPE at instant i is:

$$SPE = \sum_{k=l+1}^m t_{ik}^2 \quad (9)$$

181 The theoretical threshold of SPE at significance level α is:

$$\delta_\alpha^2 = \xi \chi_{h,\alpha}^2 \quad (10)$$

182 where $\xi = \gamma_2/\gamma_1$, $h = \text{integer}(\gamma_1^2/\gamma_2)$, $\text{integer}(o)$ is the integer value of o and
 183 $\chi_{h,\alpha}$ is the Chi-square distribution with h degrees of freedom. The constant
 184 γ_c is calculated as $\gamma_c = \sum_{k=l+1}^m \lambda_k^c$ and λ_k^c is the k^{th} eigenvalue to the c^{th}
 185 power ($c=\{1,2\}$).

186 2.3.3. Jensen-Shannon divergence

187 Jensen Shannon divergence (JSD) is a sensitive technique based on Shan-
 188 non entropy excess of a couple of distributions in regard to the mixture of
 189 their respective entropies [and without assumptions on their types](#) [41]. Con-
 190 sidering $\mathbf{f}(t)$ and $\mathbf{q}(t)$ are continuous probability density functions (pdfs)
 191 corresponding to the random variable t , JSD is the increment of the Shan-
 192 non entropy. It is defined by a function of the Shannon entropy (S_E) and its
 193 value is denoted D_{JS} such as:

$$D_{JS}(\mathbf{f}, \mathbf{q}) = S_E \left[\frac{\mathbf{f} + \mathbf{q}}{2} \right] - \frac{S_E(\mathbf{f}) + S_E(\mathbf{q})}{2} \quad (11)$$

194 The JSD can be also written as the symmetric operation of the Kullback-
 195 Leibler information theoretical function denoted as:

$$D_{JS}(\mathbf{f}, \mathbf{q}) = \frac{1}{2} I(\mathbf{f}||\mathbf{M}) + \frac{1}{2} I(\mathbf{q}||\mathbf{M}) \quad (12)$$

196 where $M = \frac{1}{2}(\mathbf{f} + \mathbf{q})$ is a mixture distribution, I is the Kullback-Leibler
 197 information [42] defined as:

$$I(\mathbf{f}||\mathbf{q}) = \int \mathbf{f}(t) \log \frac{\mathbf{f}(t)}{\mathbf{q}(t)} dt \quad (13)$$

198 As the divergence has no closed-form, the integral function (13) is numer-
 199 ically calculated using the Monte-Carlo approximation.

200 Otherwise, when the divergence value is theoretically equal to zero, it
 201 means that the two considered probability density functions are exactly the
 202 same: the reference one and the tested one are both obtained in healthy
 203 condition. In real life applications and experimentally measured data, these
 204 two distributions won't be exactly the same. Due to the environmental nui-
 205 sances, the two functions will be slightly different: this will lead to a low
 206 non-zero divergence due to the random noises. To proceed to an efficient
 207 decision and accurately highlight whether the incipient crack exists, the de-
 208 tection must be done with respect to a given threshold. This threshold is
 209 settled by evaluating the JSD on the pdfs for the process data in healthy
 210 conditions. Below this threshold, a minimized number of false alarms must
 211 be considered meaning that there will be a reduced number of false informa-
 212 tion about the presence of an incipient crack. At the same time, a maximized
 213 number of true detection of a considered incipient crack should be obtained.
 214 The evolution of this threshold is then carried out with the receiver operating
 215 curve representation highlighting the detection performances.

216 3. Incipient Fault Detection

217 3.1. Fault detection theoretical model

218 As mentioned in the previous section 2, PCA is first applied as the pre-
 219 processing method and feature extraction method. Let's denote \mathbf{q}_k and \mathbf{f}_k
 220 the pdfs of the first l principal score obtained in faulty and healthy con-
 221 ditions respectively. For Gaussian distributed signals, we can assume that
 222 the principal scores are Gaussian distributed. Then, $\mathbf{f}_k \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and
 223 $\mathbf{q}_k \sim \mathcal{N}(\mu_2, \sigma_2^2)$, where μ_1, μ_2 are the means and σ_1^2, σ_2^2 are the variances.
 224 The mixture distribution M_k is computed by $M_k = \frac{1}{2}(\mathbf{q}_k + \mathbf{f}_k)$.

225 In the PCA's model, the mean of the distribution is supposed unchanged
 226 after the incipient fault occurrence [25, 43] and described in (14).

$$\mu_1 = \mu_2 \quad (14)$$

227 And for two normally distributed functions sharing the same mean, the com-
 228 bined distribution is unimodal [44]. In the particular case of incipient fault
 229 detection, the change on the pdf induced by the incipient fault is very slight.
 230 Thus, we can consider the assumption that the mixture distribution M_k is
 231 still normally distributed, such as $M_k \sim \mathcal{N}(\mu_M, \sigma_M^2)$. The mean μ_M and the
 232 variance σ_M^2 of M_k can be calculated in (15) and (16):

$$\mu_M = \frac{1}{2}(\mu_1 + \mu_2) \quad (15)$$

233

$$\sigma_M^2 = \mathbb{E}(\mathbf{t}^2) - \mathbb{E}(\mathbf{t})^2 = \frac{1}{2}\sigma_1^2 + \frac{1}{2}\sigma_2^2 \quad (16)$$

234 The expression of the JSD under the Gaussian distribution assumption
 235 is:

$$D_{JS_{An}}(\mathbf{f}, \mathbf{q}) = \frac{1}{4}[\log \frac{\sigma_M^4}{\sigma_1^2 \sigma_2^2} + \frac{\sigma_1^2 + \sigma_2^2 + \frac{1}{2}(\mu_1 - \mu_2)^2}{\sigma_M^2} - 2] \quad (17)$$

236 In the latter, the variances σ_1^2 and σ_2^2 in (17) can be rewritten considering
 237 the component data variance and the additive noise ones such as:

$$\sigma_1^2 = \lambda_k^* + \sigma_v^2 \quad \sigma_2^2 = \tilde{\lambda}_k + \sigma_v^2 \quad (18)$$

238 where λ_k^* and $\tilde{\lambda}_k$ are the eigenvalues of the k^{th} latent score under healthy
 239 and faulty conditions without noise, respectively. σ_v^2 is the variance of the
 240 additive noise.

241 We assume that there is a relation between $\tilde{\lambda}_k$ and λ_k^* :

$$\tilde{\lambda}_k = \lambda_k^* + \Delta\lambda_k \quad (19)$$

242 where $\Delta\lambda_k$ is the eigenvalue bias due to incipient the fault occurrence.

243 Combining (16), (18) with (19), the variance of M_k is obtained:

$$\sigma_M^2 = \frac{1}{2}(2\lambda_k^* + \Delta\lambda_k + 2\sigma_v^2) \quad (20)$$

244 Based on (14), (16) and (20), equation (17) can be transformed into:

$$D_{JS_{An}}(\mathbf{f}, \mathbf{q}) = \frac{1}{4} \log \frac{(2\lambda_k^* + \Delta\lambda_k + 2\sigma_v^2)^2}{4(\lambda_k^* + \sigma_v^2)(\lambda_k^* + \Delta\lambda_k + \sigma_v^2)} \quad (21)$$

245 The obtained equation (21), clearly shows the relation between $\Delta\lambda_k$ and the
 246 JSD value.

247 3.2. Incipient fault detection performances results and discussion

248 The traditional multivariate AR system with Gaussian distributed data
 249 is used as an example to evaluate the detection performance of T^2 , SPE and
 250 JSD. We consider:

$$\mathbf{x}(i) = \begin{bmatrix} 0.118 & -0.191 \\ 0.847 & 0.264 \end{bmatrix} \mathbf{x}(i-1) + \begin{bmatrix} 1 & 2 \\ 3 & -4 \end{bmatrix} \mathbf{u}(i-1) \quad (22)$$

$$\mathbf{y}(i) = \mathbf{x}(i) + \mathbf{v}(i) \quad (23)$$

252 where \mathbf{u} is the correlated input

$$\mathbf{u}(i) = \begin{bmatrix} 0.811 & -0.226 \\ 0.477 & 0.415 \end{bmatrix} \mathbf{u}(i-1) + \begin{bmatrix} 0.193 & 0.689 \\ -0.320 & -0.749 \end{bmatrix} \mathbf{w}(i-1) \quad (24)$$

253 $\mathbf{w}(i) = [w_1(i) \ w_2(i)]^\top$ is the input vector built with two uncorrelated Gaus-
 254 sian signals with zero mean and unit variance. $\mathbf{u}(i) = [u_1(i) \ u_2(i)]^\top$ is
 255 the measured input vector. $\mathbf{y}(i) = [y_1(i) \ y_2(i)]^\top$ is the output vector and
 256 $\mathbf{v}(i) = [v_1(i) \ v_2(i)]^\top$ is the noise vector which built with two uncorre-
 257 lated Gaussian noise signals with zero mean and variance σ_v^2 . The ma-
 258 trix \mathbf{X} is formed with the AR measured inputs and outputs at instant i
 259 with $i = 1 \dots N$, i.e. $\mathbf{X} = [\mathbf{y}_1 \ \mathbf{y}_2 \ \mathbf{u}_1 \ \mathbf{u}_2]^\top$. Where each vectors \mathbf{y}_c
 260 and \mathbf{u}_c can be respectively written as $\mathbf{y}_c = [y_c(1), \dots, y_c(i), \dots, y_c(N)]^\top$ and
 261 $\mathbf{u}_c = [u_c(1), \dots, u_c(i), \dots, u_c(N)]^\top$ with $c = \{1, 2\}$.

262 After the application of PCA, we obtain four principal components with
 263 the following eigenvalues $\text{diag}(\mathbf{\Lambda}) = [40.26, 4.9, 1.14, 0.17]$. The correspond-
 264 ing percent of variance for the four PCs are then $[86.64, 10.54, 2.45, 0.37]$. So,
 265 the first PC contains 86.64% of the original data overall information and the
 266 CPV of the first two is 97.18%. With respect to equation (6), the principal
 267 subspace is then composed of the first two principal components and the
 268 residual one with the last two components. So, for this validation study, the
 269 detection process using T^2 is then based on the first two principal component
 270 scores and SPE is evaluated using the last two components. For our proposal
 271 using JSD, we will focus only on the first principal component which contains
 272 a sufficiently significant part of the data information (86.64%).

273 Based on the mentioned fault model, assuming that the fault affects the
 274 last 10% samples of \mathbf{y}_2 , we have $y_2(i) = (1+g)x_2(i) + v_2(i)$. Thus, to highlight
 275 the detection capabilities, we have affected \mathbf{x}_2 with a fault corresponding to
 276 80% bias on the signal amplitude in the last 100 samples of \mathbf{x}_2 with $N = 1000$

277 and $SNR = 40dB$. For the T^2 test and SPE, the detection is evaluated on
 278 each sample i but for JSD, the results are obtained by doing 900 realisations
 279 of the healthy conditions and 100 realisations of the faulty ones. The results
 280 are displayed in Fig.2. The obtained detection results can then be compared.

Figure 2: Fault detection performances of JSD, T^2 and SPE

281 It is noted from this example that JSD is superior to the other criteria T^2
 282 and SPE. Even when the fault severity is very high, the detection with T^2
 283 and SPE reveals numerous false alarms and missed detections. For a given
 284 $P_{FA} = 0.05$ the P_D evaluated for T^2 , SPE and JSD are respectively 0.63,
 285 0.07 and 1. Indeed for smallest fault severities, T^2 and SPE will exhibit
 286 poorer performances compared to JSD.

287 According to equation (21), the detection performances of the proposed
 288 methodology are largely affected by the evolution of the noise level. To
 289 highlight this purpose, we propose to evaluate these performances considering
 290 the noise level compared to the original signal power (signal to noise ratio
 291 i.e. SNR) or the fault power (fault to noise ratio i.e. FNR) defined as:

$$FNR = 10 \cdot \log_{10} \frac{\sigma_f^2}{\sigma_v^2} \quad (25)$$

$$SNR = 10 \cdot \log_{10} \frac{\sigma_s^2}{\sigma_v^2} \quad (26)$$

292 where σ_f^2 is the fault power, σ_s^2 is the signal power and σ_v^2 is the noise power.

293 Considering that the noise can mask the incipient fault, the comparative
294 study is first done by setting the SNR to 40dB and varying the fault severity.
295 The detection performances results for the incipient fault of T^2 , SPE, and
296 JSD for different FNR are displayed in Fig.3.

297 It is clear that the detection performances of T^2 and SPE are widely
298 degraded with the decrease of FNR (i.e. lower fault severity can be obtained
299 at a given noise level).

300 It is demonstrated that T^2 and SPE are totally inefficient for incipient
301 fault detection. Their detection performances are only acceptable for large
302 FNR values (e.g. FNR is 65dB) that is corresponding to large fault severities.

303 Conversely, JSD shows excellent performances for incipient faults detec-
304 tion. The probability of detection is $P_D = 1$ even when $FNR = 5$ dB. For
305 lower fault severities the performances are still good for $FNR = -5$ dB but for
306 FNR values lower than -10 dB the detection is more tedious.

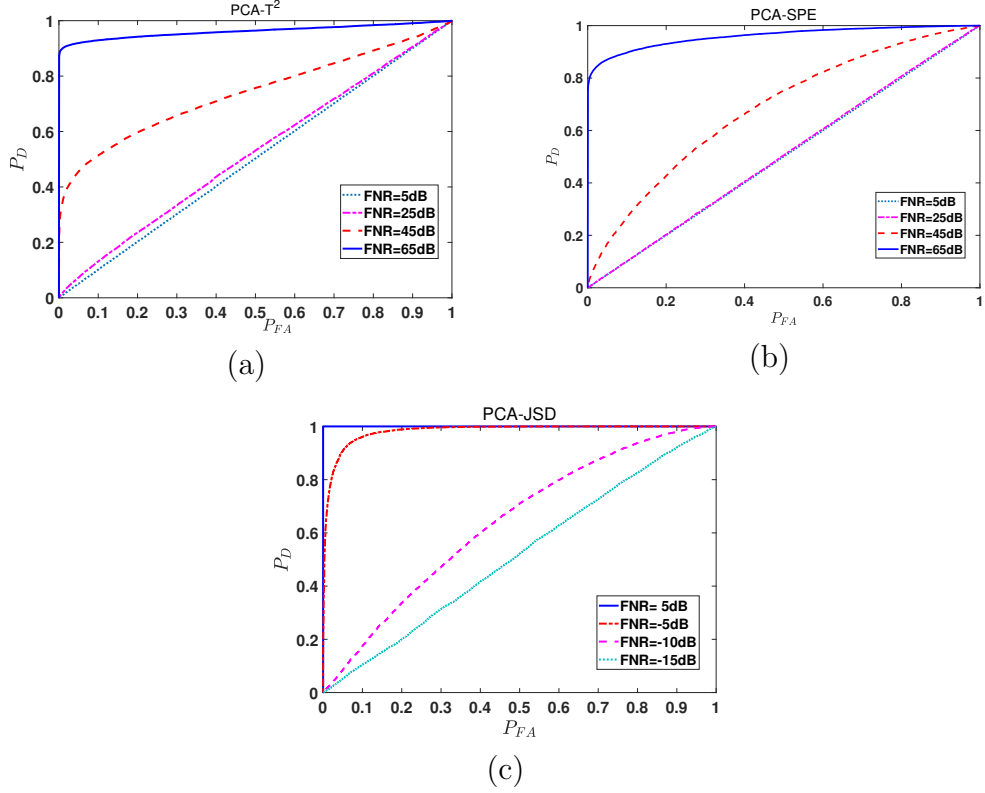

Figure 3: Fault detection performances considering different FNR with SNR=40dB for: (a) T^2 , (b) SPE and (c) JSD

307 In order to show the impact of noise factors on the detection capabil-
 308 ities of JSD, we consider a fault severity $g = 0.02$. The detection results
 309 versus different SNR are given in Fig.4. JSD has high efficiency with 100%
 310 detection capability for the low noise levels (SNR>35dB) with a very low
 311 false alarm probability. For the high noise levels (SNR<30dB), the detection
 312 performances of JSD are affected by the noise. The fault detection perfor-
 313 mances of JSD decrease distinctly along with the SNR decreases (the noise
 314 levels increase).

Figure 4: Fault detection results of JSD for different SNR, $g = 0.02$

JSD is then efficient for the detection of incipient faults but its performances are clearly affected when the noise level is very important compared to the fault severity one.

3.3. Application to nondestructive incipient cracks detection

Material crack detection becomes more and more important for industrial system and structures. The Eddy Current Testing (ECT) technique is a widely used measurement approach. It is based on the measurement of the magnetic field effects (induced voltage and current flowing in an excitation coil) [31]. In Fig.5 we show an example of the change induced on the eddy currents trajectory in a conductive material with the presence of a surface crack.

Figure 5: Effect of the presence of a crack on Eddy currents trajectory

326 Then, from these measurements, the evolution of the impedance with the
 327 presence of the crack Z_f is obtained and can be written as:

$$Z_f = Z_h + \delta Z = R_f + jY_f \quad (27)$$

328 where the R_f and Y_f are respectively the real and imaginary parts of the
 329 indexed impedance Z_f . The remaining δZ is the evolution of the healthy
 330 impedance Z_h due to the presence of the crack. As an example, Fig.6 repre-
 331 sents the evolution of the imaginary part of the impedance for a conductive
 332 material containing cracks with $d = 400\mu m$ depth and 2 different lengths
 333 $l = 400\mu m$ and $l = 600\mu m$ with a 2 MHz excitation frequency. The presence
 334 of the crack is clearly visible through the variation of the impedance.

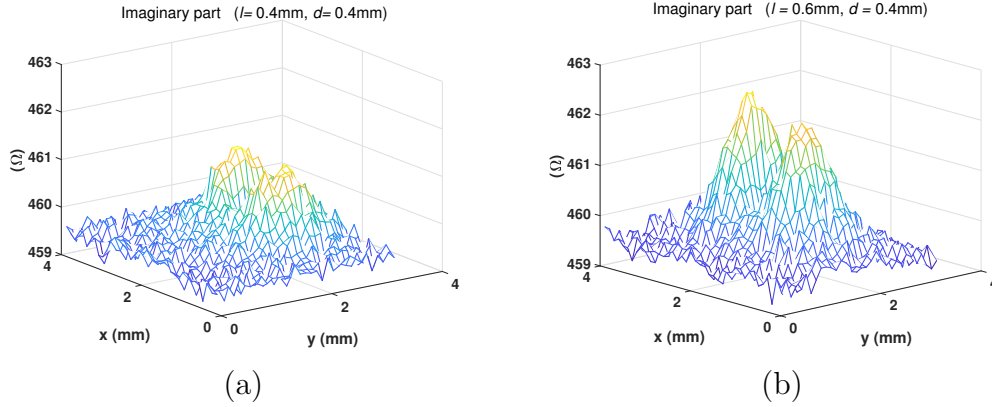

Figure 6: Imaginary part of the impedance of the ECT map for big cracks with sizes: (a) $l = 0.4mm$ and $d = 0.4mm$, (b) $l = 0.6mm$ and $d = 0.4mm$

335 However, in the case of smaller cracks (incipient ones), these impedance
 336 variations can be partially masked by the presence of environmental nuisance.
 337 In Fig.7 we show the evolution of the imaginary part of the impedance in the
 338 case of cracks with length or depth equal to $100\mu m$ or $200\mu m$. The evolution
 339 of the impedance value does not significantly disclose the presence of these
 340 minor cracks due to the nuisances. Therefore, we propose, in this work,
 341 to use of the Jensen-Shannon divergence to detect these incipient faults by
 342 analysing these slight impedance variation. These impedance variations will
 343 cause slight changes in the faulty probability distribution compared to the
 344 healthy reference one and are then evaluated by using the JSD.

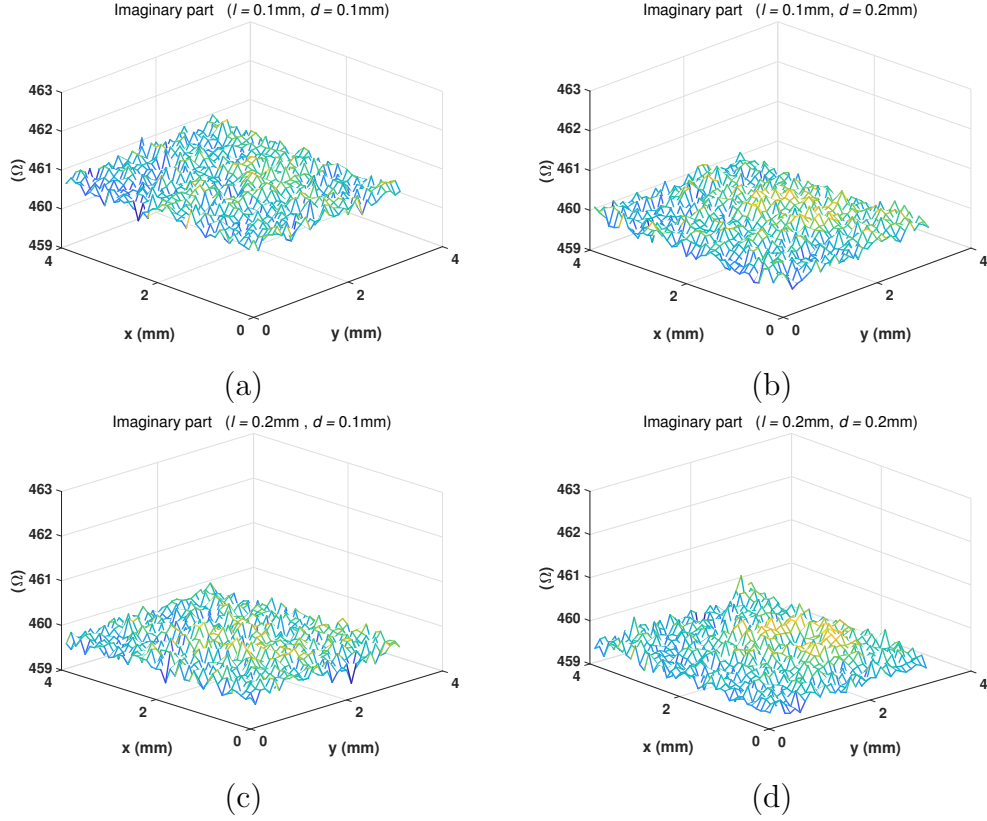

Figure 7: Imaginary part of the impedance of the ECT map for minor crack sizes: (a) $l = 0.1\text{mm}$ and $d = 0.1\text{mm}$, (b) $l = 0.1\text{mm}$ and $d = 0.2\text{mm}$, (c) $l = 0.2\text{mm}$ and $d = 0.1\text{mm}$, (d) $l = 0.2\text{mm}$ and $d = 0.2\text{mm}$

In our work, we consider the complex impedance values obtained from an ECT experimental system.

We mainly focus on incipient cracks such as their length (l) or depth (d) are equal to $100\mu\text{m}$ and $200\mu\text{m}$ in several combinations. The perturbation level will be considered using several SNR values in the range $[0, 20\text{dB}]$. The considered crack size for this study are then summarized in the following table:

Table 1: Considered crack sizes		
Cracks	length (l)	depth (d)
C_1	$0.1mm$	$0.1mm$
C_2	$0.1mm$	$0.2mm$
C_3	$0.2mm$	$0.1mm$
C_4	$0.2mm$	$0.2mm$

352 To apply our diagnosis procedure, complex impedance data obtained in
 353 the healthy and the faulty conditions and considered as impedance maps
 354 with size 40×32 . In our study, we focus only the imaginary part of the
 355 impedance that are known to be more sensitive to the presence of the cracks.
 356 These values of the ECT map are arranged into a single row vector (1×1280)
 357 and are then normalized. A reference map with healthy impedance values
 358 created. We enlarge each normalized ECT map (40×32) to a larger map
 359 (420×100) so that we can get the sufficient data and reduce the false alarms
 360 caused by the internal and external perturbations. For both healthy and
 361 faulty conditions 100 realisations were evaluated.

362 In Fig.8, we present the evolution of the JSD and the mean of the nor-
 363 malized impedance in healthy and faulty conditions for the crack sizes C_1
 364 and C_2 in a 20dB SNR environment. The dashed red lines are the thresholds
 365 of the JSD and the mean calculated at 99% of their maximum values in the
 366 healthy conditions.

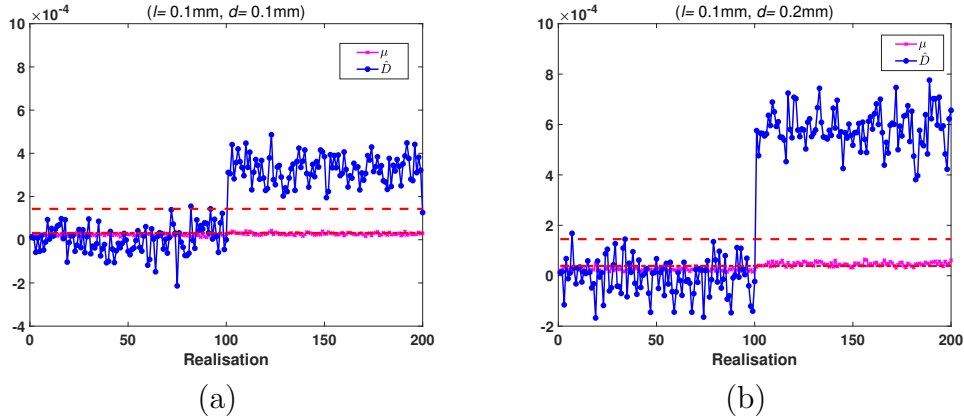

Figure 8: JSD and mean detection capabilities for the minor cracks size: (a) C_1 , (b) C_2

367 This result confirms that the mean fails to detect the crack with size C_1
 368 ($P_D = 0.24$ and $P_{FA} = 0.01$). For the crack size C_2 , lots of missed detections

are obtained ($P_D = 0.84$ and $P_{FA} = 0.01$). However, with the JSD, satisfying detection capabilities are obtained for both considered crack sizes ($P_D = 1$ and $P_{FA} = 0.03$).

In Fig.9 and Fig.10 we present the detection performances of JSD for the four considered incipient cracks sizes C_1 , C_2 , C_3 , C_4 with different perturbation levels.

Figure 9: JSD detection performances for different perturbation level and for incipient cracks sizes: (a) C_1 and (b) C_2

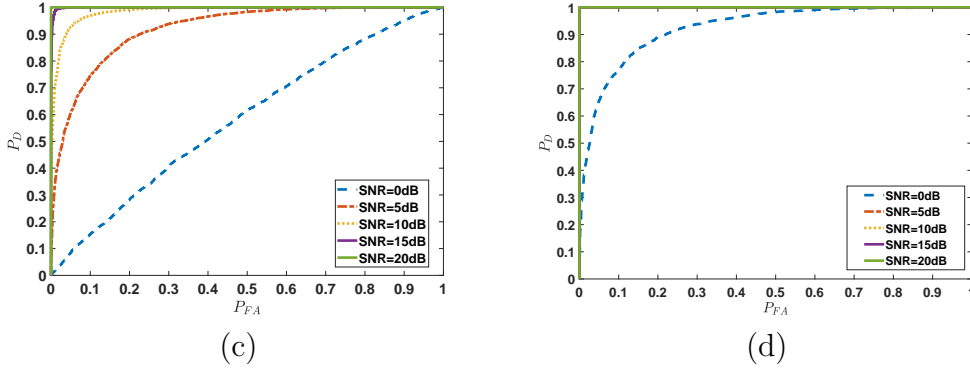

Figure 10: JSD detection performances for different perturbation levels and incipient cracks sizes: (c) C_3 and (d) C_4

The Figs clearly illustrate that the JSD has good detection performances for these incipient cracks when the SNR is larger than 10dB even when the crack size is $l = 0.1mm, d = 0.1mm$ (C_1). These detection capabilities

378 increase along with the SNR values. The JSD offers perfect detection perfor-
 379 mances ($P_D = 1$ with $P_{FA} = 0$) even for the smallest considered crack size
 380 (C_1) when the SNR is 20dB. This particular SNR value corresponds to the
 381 condition that the plate is smooth and the environmental perturbations are
 382 well isolated.

383 The perturbations that can be caused by internal or external factors (low
 384 SNR values) have a large effect on the JSD detection performances. It can be
 385 clearly noticed from Fig.9-a that the JSD is not efficient for the detection of
 386 the most incipient considered cracks size C_1 when SNR=0dB. However, when
 387 the crack size increases, the detection capabilities of JSD at 0dB increases
 388 (see Fig.9-b, Fig.10-c and Fig.10-d).

389 4. Incipient Fault Estimation

390 4.1. Fault estimation theoretical model

391 Based on equation (19) the fault severity g can be determined as a func-
 392 tion of $\tilde{\lambda}_k$ and it is infinitely derivable in the neighbourhood of $g \approx 0$, The
 393 Taylor development of $\tilde{\lambda}_k$ can be written as:

$$\tilde{\lambda}_k = \lambda_k^* + \frac{\partial \tilde{\lambda}_k}{\partial g}(0)g + \frac{1}{2} \frac{\partial^2 \tilde{\lambda}_k}{\partial g^2}(0)g^2 + \dots \quad (28)$$

394 In our study, the PCA is based on the covariance matrix \mathbf{S} denoted as:

$$\mathbf{S} = \frac{1}{N-1} \bar{\mathbf{X}}^T \bar{\mathbf{X}} = \frac{1}{N-1} \begin{bmatrix} \bar{\mathbf{x}}_1^T \bar{\mathbf{x}}_1 & \cdots & \bar{\mathbf{x}}_1^T \bar{\mathbf{x}}_j & \cdots & \bar{\mathbf{x}}_1^T \bar{\mathbf{x}}_m \\ \vdots & & \vdots & & \vdots \\ \bar{\mathbf{x}}_j^T \bar{\mathbf{x}}_1 & \cdots & \bar{\mathbf{x}}_j^T \bar{\mathbf{x}}_j & \cdots & \bar{\mathbf{x}}_j^T \bar{\mathbf{x}}_m \\ \vdots & & \vdots & & \vdots \\ \bar{\mathbf{x}}_m^T \bar{\mathbf{x}}_1 & \cdots & \bar{\mathbf{x}}_m^T \bar{\mathbf{x}}_j & \cdots & \bar{\mathbf{x}}_m^T \bar{\mathbf{x}}_m \end{bmatrix} \quad (29)$$

395 where:

$$\bar{\mathbf{x}}_j = \mathbf{x}_j - \mu_j^{\mathbf{1}} = (\mathbf{x}_j^* - \mu_j^{*\mathbf{1}}) + (\mathbf{F}_j - g \times \frac{1}{N} \sum_{i=b}^N x_{ij}^{*\mathbf{1}}) + \mathbf{v}_j \quad (30)$$

396 where $\mathbf{1}$ is a column vector of N ones.

397 The first order derivative of the eigenvalue $\tilde{\lambda}_k$ can be calculated as:

$$\begin{aligned} \frac{\partial \tilde{\lambda}_k}{\partial g} &= \mathbf{p}_k^{*\top} \frac{\partial \mathbf{S}}{\partial g} \mathbf{p}_k^* \\ &= \frac{2}{N-1} \left(p_{jk} \sum_{r=1}^m p_{rk} \sum_{i=b}^N (x_{ir}^* - \mu_r^*) x_{ij}^* + p_{jk}^2 \sum_{i=b}^N (x_{ij}^* - \frac{1}{N} \sum_{i=b}^N x_{ij}^*)^2 \times g \right) \end{aligned} \quad (31)$$

398 where \mathbf{p}_k^* is the eigenvector associated to λ_k^* in faultless and noise-free con-
399 dition.

400 The second order derivative of $\tilde{\lambda}_k$ can be obtained as:

$$\frac{\partial^2 \tilde{\lambda}_k}{\partial g^2} = \mathbf{p}_k^{*\top} \frac{\partial^2 \mathbf{S}}{\partial g^2} \mathbf{p}_k^* = \frac{2}{N-1} \left(p_{jk}^2 \sum_{i=b}^N (x_{ij}^* - \frac{1}{N} \sum_{i=b}^N x_{ij}^*)^2 \right) \quad (32)$$

401 if we denote that:

$$a_1 = p_{jk} \sum_{r=1}^m p_{rk} \left(\sum_{i=b}^{N-1} (x_{ir}^* - \mu_r^*) x_{ij}^* \right) \quad (33)$$

$$a_2 = 3p_{jk}^2 \sum_{i=b}^N \left(x_{ij}^* - \frac{1}{N} \sum_{i=b}^N x_{ij}^* \right)^2 \quad (34)$$

403 Choosing the first two derivative order of the equation (28) we obtain the
404 following equation:

$$\Delta \lambda_k = \frac{2}{N-1} a_1 \times g + \frac{1}{N-1} a_2 \times g^2 \quad (35)$$

405 Then, the theoretical fault estimation expression can be obtained by find-
406 ing the positive solution of (35):

$$\hat{g} = \frac{-a_1 + \sqrt{a_1^2 + (N-1)a_2 \Delta \lambda_k}}{a_2} \quad (36)$$

407 In order to obtain the fault amplitude estimation equation, we must cal-
408 culate the equation of $\Delta \lambda_k$ corresponding to the JSD values. As equation
409 (21) can be seen as a function of $\Delta \lambda_k$ and it is infinitely derivable in the
410 neighborhood of zero, the Taylor development of D_{JS} can be given following
411 (37).

$$D_{JS}(\Delta\lambda_k) = D_{JS}(0) + \frac{\partial D_{JS}(\Delta\lambda_k)}{\partial \Delta\lambda_k}(0)\Delta\lambda_k + \frac{1}{2} \frac{\partial^2 D_{JS}(\Delta\lambda_k)}{\partial \Delta\lambda_k^2}(0)\Delta\lambda_k^2 + \dots \quad (37)$$

412 We obtain its first order derivative (38) and second order derivative (39)
413 based on (21).

$$a_3 = \frac{\partial D_{JS}(\Delta\lambda_k)}{\partial \Delta\lambda_k} = \frac{1}{4} \left[\frac{2}{2\lambda_k^* + \Delta\lambda_k + 2\sigma_v^2} - \frac{1}{\lambda_k^* + \Delta\lambda_k + \sigma_v^2} \right] \quad (38)$$

$$a_4 = \frac{\partial^2 D_{JS}(\Delta\lambda_k)}{\partial \Delta\lambda_k^2} = \frac{1}{4} \left[\frac{1}{(\lambda_k^* + \Delta\lambda_k + \sigma_v^2)^2} - \frac{2}{(2\lambda_k^* + \Delta\lambda_k + 2\sigma_v^2)^2} \right] \quad (39)$$

414 Choosing the first two order derivatives of Taylor equation to establish
415 a quadratic equation (40) from which the resolution can derive the approxi-
416 mated value of $\Delta\lambda_k$.

$$D_{JS}(\Delta\lambda_k) = D_{JS}(0) + a_3(0)\Delta\lambda_k + \frac{1}{2}a_4(0)\Delta\lambda_k^2 \quad (40)$$

417 In healthy conditions, the variance change $\Delta\lambda_k$ is 0, and $a_3(0)$ and $a_4(0)$
418 can be simplified as in (41). Then we find the solution given in (42).

$$a_3(0) = 0 \quad a_4(0) = \frac{1}{4} \left[\frac{1}{(\lambda_k^* + \sigma_v^2)^2} - \frac{2}{(2\lambda_k^* + 2\sigma_v^2)^2} \right] \quad (41)$$

419

$$\Delta\lambda_k = \sqrt{\frac{2\hat{D}_{JS}}{a_4(0)}} \quad (42)$$

420 Finally, the approximated theoretical estimation of the fault severity \hat{g}
421 can be obtained by combining (36) and (42) such as:

$$\hat{g} = \frac{-a_1 + \sqrt{a_1^2 + (N-1)a_2(\sqrt{\frac{2\hat{D}_{JS}}{a_4(0)}})}}{a_2} \quad (43)$$

422 where \hat{D}_{JS} in (43) is calculated using Monte Carlo Simulation. Based on
423 this equation (43), the fault severity can be estimated using the JSD value.

4.2. Incipient Fault estimation performances results and discussion

To verify the validity of the fault estimation model obtained in (43) for incipient fault, we plot in Fig.11 the estimated fault severity (\hat{g}) versus the real one (g) for different SNR values. For this work we have considered the same AR Model that has been used in the previous section 3.2.

The results indicate that the fault estimation obtained with this model leads to a little overestimation of the fault severity. This can be considered as a safety margin in a sensible fault diagnosis context.

Figure 11: Fault estimation results at different noise levels

Figure 12: Estimation relative error at different noise levels

The relative error ϵ_g is calculated as $\epsilon_g = \frac{\hat{g}-g}{1+g}$ for quantifying the overestimation level. The results for different SNR are presented in Fig.12. The

relative error decreases either while the fault severity or the SNR increases.
 For SNR = 25dB, the maximum error is 2.75%.

Figure 13: Estimation relative error with SNR=25dB for different FNR

The relative error results for different FNR (with SNR set at 25dB) is displayed in Fig.13. The result highlights that the maximum error is 2.15% when FNR is -21dB. Such a value is sufficiently low to be acceptable considering the incipient fault severity diagnosis context.

4.3. Application to nondestructive incipient cracks severity estimation

In order to validate the proposed estimation process, we have considered the evaluation of cracks based on experimental ECT data. The considered ECT cracks considered here are the same as those described in section 3. The fault estimation model is focused on the crack sizes given in Table 2 where the crack area increases along with the length or depth values. In this work only incipient cracks evaluation are considered. Then no cracks with an area larger than $0.24mm^2$ are evaluated here. These restrictions imply a more tedious evaluation. For the estimation model, considering such constraint, we have used the Taylor equation to be able to approximately derive some part of the equations. This leads to the assumption that the estimated value should be close to zero and not too far. While this assumption is not respected, the estimation accuracy is decreased.

For each incipient crack size, we compute the FNR value. For this latter, the noise level is related to the internal and external sources. It is obtained considering the variance of the impedance signal in healthy conditions. Assuming that the fault is independent from the noise, the fault level is considered as the main evolution between healthy and faulty signals. As shown

458 in Table 2, FNR for the smallest and biggest crack sizes are respectively
 459 -29.3dB and 0.21dB .

Table 2: Crack sizes area and corresponding experimental FNR						
Area (mm^2)	0.01	0.02	0.04	0.08	0.16	0.24
length (l), depth (d)	0.1, 0.1	0.1, 0.2	0.2, 0.2	0.4, 0.2	0.4, 0.4	0.6, 0.4
Experimental FNR(dB)	-29.3	-20.1	-16.8	-9.63	-4.5	0.21

460 For our study, we consider the reference healthy data as the ECT matrix
 461 \mathbf{X}_h denoted as $\mathbf{X}_h = (\mathbf{z}_1^h, \mathbf{z}_2^h, \mathbf{z}_3^h, \mathbf{z}_4^h)$, where \mathbf{z}^h is the enlarged imaginary part
 462 of the impedance signals acquired from the edge of the normalized map.
 463 The faulty ECT matrix \mathbf{X}_f denoted as $\mathbf{X}_f = (\mathbf{z}_1^f, \mathbf{z}_2^f, \mathbf{z}_3^f, \mathbf{z}_4^f)$, where \mathbf{z}^f is the
 464 enlarged imaginary impedance signals acquired from the faulty normalized
 465 map. The number of samples is $N = 4.2 * 10^4$.

466 The PCA is applied to \mathbf{X}_h and \mathbf{X}_f . Then the reference distribution and
 467 the faulty distribution of the first principal component scores are calculated.
 468 Fig.14 presents the probability distribution for the first principal component
 469 score \mathbf{t}_1 corresponding to the crack size C_1 . Twenty acquisitions of \mathbf{z}^f are
 470 done for each crack size. The Jensen-Shannon divergence values between a
 471 faulty distribution and the reference one are computed according to equation
 472 (12) using Monte carlo simulation. The estimated fault severities impedance
 473 values are obtained based on equation (43). In Fig.15 we plot the average
 474 estimation of the fault severity according to the crack size measured by FNR
 475 value.

Figure 14: Pdfs of \mathbf{t}_1 for the healthy and faulty component scores

Figure 15: Fault severity estimation versus the FNR(dB)

476 Fig.15 clearly shows that the estimated fault severity grows monotonically
 477 with the FNR. This result validates the effectiveness of the proposed fault
 478 estimation model.

479 5. Conclusion

480 In this paper, we have proposed an incipient fault diagnosis scheme based
 481 on the Jensen-Shannon Divergence for fault detection and estimation. For
 482 both cases, a theoretical model is proposed and widely show the dependence
 483 of the fault with the JSD and the noise level.

484 The effectiveness of the detection is first validated by using simulated
 485 data from an AR system. The detection performances of JSD for incipient
 486 fault are compared to the Hotelling's test T^2 and the SPE ones. Using ECT
 487 experimental data to detect incipient cracks in a conductive plate, JSD good
 488 performances have been obtained in terms of P_D and P_{FA} even with SNR as
 489 low as 20dB. The proposed approach allows to evaluate such incipient cracks
 490 that was not able to be detected in the literature with such noisy ECT data.

491 Concerning the fault estimation, we prove, for Gaussian distributed data,
 492 the efficiency and the accuracy of the proposal. For low noise conditions,
 493 the estimation accuracy is good, the maximum relative error is 2.75% for
 494 SNR=25dB and low fault severities (the maximum relative error is 2.15% for
 495 $FNR = -21$ dB). With our proposal, the fault severity is slightly overesti-
 496 mated particularly in high noise condition levels. This slight overestimation
 497 is a valuable safety margin in health monitoring process. Finally, the appli-
 498 cation for fault severity estimation on the ECT data proves the efficiency of

499 the derived model by providing an accurate estimation of the fault amplitude
500 versus the FNR.
