Abstract

This article focuses on the characterization of a particular spectral property called Multiplicity-induced-dominancy applying for linear dynamical systems described by delay-differential equations. More precisely, we characterize the property in the scalar neutral case with respect to the system parameters. Particular attention is paid to the so-called over-order multiplicities corresponding to real double and triple characteristic roots.

Keywords: Functional differential equations, Neutral equations, Control theory, Control design, Stability theory, Stabilization of dynamical systems, partial pole placement.

1. INTRODUCTION

Dynamical systems with delays provide useful models in a wide range of scientific and technological domains such as biology, chemistry, economics, physics, or engineering, where the presence of the delays is inherent to propagation phenomena, such as of material, energy, or information, with a finite propagation speed. Due to their numerous applications, these kinds of systems have been the subject of much attention by researchers in several fields, in particular since the 1950s and 1960s. More precisely, and to the best of the authors' knowledge, modeling propagation and transport phenomena by delay-differential algebraic equations dates back to the 50s; see, for instance, a few examples in [1], [2], [3], [4] and the references therein.

On the one hand, various electrical and fluid dynamical systems initially described by partial differential equations (PDEs) of hyperbolic type with mixed initial, and derivative boundary conditions in feedback interconnection, can be integrated along the characteristics to arrive at a set of delay differential-algebraic equations (DDAEs), i.e. coupled delay-differential equations and -difference equations in continuous-time (see, e.g. [5], [6]). For a more comprehensive introduction to the subject including a long list of references we refer to Răsvan [7]. On the other hand, the presence of a delay in the input-output channels in the case of proper dynamical systems may lead to DDAEs for the closed-loop schemes (see, e.g., [4], [8]), whose stability may be sensitive to the delay parameter as shown in [9].

An interesting property, entitled multiplicity-induced-dominancy (MID in short), which corresponds to conditions on the system's parameters for which a multiple root defines the spectral abscissa\(^1\) of the corresponding quasipolynomial. The MID property applying for the spectrum of the linear delay-differential equations (DDEs), was recently introduced in [10] and proved in [11, 12] in the generic MID case (GMID for short), which corresponds to roots whose multiplicity is equal with the degree of the corresponding quasipolynomial.

---

\(^{1}\)The spectral abscissa is defined by the real part of the rightmost root of the spectrum of the corresponding characteristic function; see, for instance, [4] and the references therein for a deeper discussion of the notion.

---

Preprint submitted to Elsevier September 5, 2023
quasipolynomial defines necessarily the spectral abscissa in both retarded and neutral cases. The GMID is shown by using an appropriate integral factorization of the corresponding quasipolynomial which appears to be nothing but a Kummer hypergeometric function (see also [13]). Such a multiplicity is called \textit{generic}, and it is always larger than the degree of the delay-free polynomial. By exploiting different properties of Whittaker (confluent hypergeometric) functions, its extension to neutral DDEs can be found in [12]. For an overview of existing methods for characterizing multiple characteristic roots we refer to [14].

As discussed in the references above, MID triggers interesting perspectives in the control area by providing a new methodology based on the so-called \textit{partial pole placement}; see, for instance, some examples and discussions in [15] on human balancing and [16] on vibration control. In our opinion, the said method is easy to implement, and gives an explicit tuning rule for a prescribed decay rate of the solutions of the closed-loop system. Finally, it should be mentioned that this method further exploits the idea of using the delay as a \textit{control parameter} (see also [17] for an overview on existing results).

To the best of the authors’ knowledge, excepting some sufficient conditions proposed by [18], there are no explicit proofs of the MID property holding in the non-generic case, and this paper offers new insights for a better understanding of the property. With the remarks above, the aim of this paper is twofold. First, a full characterization of the MID property in the case of scalar neutral systems in both generic and non-generic cases is carried out. Indeed, if the generic case corresponds to the triple characteristic root located on the real axis (see, e.g., [11], [12]), the non-generic case (double root) corresponds to the so-called \textit{over-order (intermediate) multiplicity}\footnote{multiplicity larger than the degree of the corresponding polynomial in the delay-free case and smaller than the degree of the quasipolynomial} (IMID). Surprisingly, although the stability of the scalar neutral DDE was fully addressed in the open literature and complete characterization of the stability regions in the parameter space exists (see, for instance, [19, 8, 1, 2, 3], however, the link between the multiplicity of the real roots and the corresponding spectral abscissa was not explicitly characterized. However, it should be mentioned that, in characterizing the stability charts in the scalar neutral DDE case, Wright [20] observed that the characteristic function can have three real roots but there is no an explicit discussion regarding double and/or triple real characteristic roots.

Second, in the non-generic case (that is, double and triple real roots), the analysis exhibits the advantages and the limitations of the MID with respect to the corresponding “free” parameter and reinforces the idea that the delay, seen as a \textit{control parameter}, can be beneficial in closed-loop.

The remaining of the paper is organized as follows. Some preliminary results as well as a motivating example are presented in Section 2. Section 3 includes the main results as well as various discussions on the over-order multiplicities (double and triple characteristic real roots). Some remarks conclude the paper.

Throughout this paper, the following notations are used: $\mathbb{R}(\mathbb{R}^+)$ and $\mathbb{C}$ denote the sets of real (positive) numbers and the set of complex numbers, respectively. For a complex number $\lambda$, $\Re(\lambda)$ ($\Im(\lambda)$) denote its real (imaginary) part. Finally, for a (quasi)polynomial $P(\cdot)$, $\deg(P)$ denotes its degree.

2. \textbf{PREREQUISITES}

In the study of linear time-invariant (LTI) dynamical delay systems, we deal with transfer functions involving quasipolynomials, which are defined hereafter.

\textbf{Definition 2.1.} A \textit{quasipolynomial} is a particular entire function $\Delta : \mathbb{C} \times \mathbb{R}^k \mapsto \mathbb{C}$ which may be written as follows

$$\Delta(s; \tau_1, \ldots, \tau_k) = \sum_{i=0}^{k} P_i(s) e^{-\tau_is},$$

where $k$ is a positive integer, $\tau_i$ ($i = 0..k$) are pairwise distinct non-negative real numbers and $P_i$ ($i = 0..k$) are polynomials of degree $d_i \geq 0$. The degree $D$ of the quasipolynomial $\Delta$ is equal to the sum of the degrees of the involved polynomials $P_i$ plus the number of delays, i.e.,

$$D = k + \sum_{i=0}^{k} d_i.$$
An important result in the open literature, known as Polyá-Szego bound, shows that there exists an explicit link between the degree of a quasipolynomial and the number of its roots in horizontal strips of the complex plane \( \mathbb{C} \).

**Proposition 2.1.** [21, Problem 206.2, page 144 and page 347]. Let \( \Delta \) be a quasipolynomial of degree \( D \) as in (1), and \( \alpha, \beta \in \mathbb{R} \) satisfy \( \alpha \leq \beta \). If \( M \) is the number of roots of \( \Delta \) contained in the set \( \{ s \in \mathbb{C} \mid \alpha \leq \Im(s) \leq \beta \} \) counting multiplicities, then
\[
\frac{(\tau_k - \tau_0)(\beta - \alpha)}{2\pi} - D \leq M \leq \frac{(\tau_k - \tau_0)(\beta - \alpha)}{2\pi} + D.
\]

Furthermore, for a given root \( s_0 \in \mathbb{C} \) of a quasipolynomial \( \Delta \), one obtains the following link between the multiplicity of \( s_0 \) and the degree of \( \Delta \).

**Corollary 2.1.** Let \( \Delta \) be a quasipolynomial of degree \( D \). Then, any root \( s_0 \in \mathbb{C} \) of \( \Delta \) exhibits a multiplicity at most equal to \( D \).

**Remark 2.1.** Corollary 2.1 is obtained immediately by letting \( \alpha = \beta = \Im(s_0) \) in Proposition 2.1. Notice also that Polyá-Szego bound has been recovered in [22] using a constructive approach based on functional Birkhoff matrices. Furthermore, if some coefficients of the polynomials \( P \) defined in (1) vanish, then a sharper bound for the multiplicity is provided in [22].

In what follows, we give a precise definition of the dominant root.

**Definition 2.2.** A spectral eigenvalue (root) \( s_0 \) is said to be a dominant (respectively, strictly dominant) root of \( \Delta \), if the following inequality holds \( \Re(\xi) \leq \Re(s_0) \) (respectively, \( \Re(\xi) < \Re(s_0) \)) for any \( \xi \in \mathbb{C} \setminus \{ s_0 \} \), a distinct eigenvalue (root) of \( \Delta \).

2.1. **Motivating example: Feedback stabilization for a scalar conservation law with PI boundary control**

Consider the problem of stabilization of solutions of a dynamical system described by partial differential equations. More precisely, we revisit the problem of exponential stabilization of the following scalar conservation law proposed in [23, 12]:
\[
\partial_t \varphi(t, x) + \lambda \partial_x \varphi(t, x) = 0, \quad t \in [0, \infty), \quad x \in (0, L),
\]  
(2)

where \( L > 0 \) and \( \varphi(t, x) \) denotes the system state at position \( x \in (0, L) \) and in time \( t \in [0, +\infty) \). As considered in [23], the value \( \lambda \), which denotes the velocity of propagation, is assumed to be a positive constant. Equation (2) comes with a boundary condition under the form of a PI controller:
\[
\varphi(t, 0) = k_p \varphi(t, L) + k_i \int_0^t \varphi(v, L) dv,
\]  
(3)

where \( k_p \) and \( k_i \) are the feedback parameters representing “proportional” and “integral” control gains. Applying the Laplace transform to both sides of the boundary condition and multiplying by \( s \), one obtains the closed-loop characteristic function
\[
\Delta(s) = s - (k_i + k_p s) e^{-\frac{L}{\lambda} s},
\]  
(4)

which corresponds to the characteristic function of a first-order neutral DDE. In this case, the degree \( \nu_{PS} \) of \( \Delta \) is equal to 3 and, as mentioned in [12], the maximal multiplicity can be achieved only by a root on the real axis.

Next, by exploiting the results of Theorem 3.1, Theorem 3.6, and Theorem 3.10 from [12], or Theorem 4 from [24], we conclude that forcing a triple spectral value guarantees its dominance as a root of (4), and then the exponential stability of solutions of (2)-(3). More precisely, by tuning the controller gains as
\[
k_p = -e^{-2}, \quad k_i = -\frac{4e^{-2}\lambda}{L},
\]  
(5)
one achieves the unique admissible triple root, which is \( s_0 = -\frac{2\lambda}{\tau} \) and corresponds to the decay rate of solutions of (2)–(3). Furthermore, as shown in Theorem 3.10 from [12], the set of roots of \( \Delta \) is \( \left\{ s_0 + \frac{i\lambda}{\tau} \zeta \mid \zeta \in \Xi_1 \right\} \) where \( \Xi_1 = \left\{ \zeta \in \mathbb{R} \mid \tan \left( \frac{\zeta}{2} \right) = \frac{\zeta}{2} \right\} \). Figure 1(a) shows the result of a numerical computation of the roots of (4) with the parameters (5), while Figure 1(b) shows the solution of (2)–(3) in the case \( \frac{\zeta}{2} = 1 \) with an initial condition \( \varphi(0, x) = \sin(2\pi x) \).

Figure 1: (a) Spectrum distribution of (4) and (b) solution of (2) with initial condition \( \varphi(0, x) = \sin(2\pi x) \), with \( \frac{\zeta}{2} = 1 \) and parameters \( k_p \) and \( k_i \) satisfying (5). Figure taken from [12].

3. Main Results

3.1. First-order neutral equation

Under appropriate initial conditions, consider the following scalar neutral DDE:

\[
\dot{x}(t) + a_0 x(t) + \alpha_1 \dot{x}(t - \tau) + a_0 x(t - \tau) = 0
\]

with four (real) parameters \((a_0, \alpha_1) \in \mathbb{R}^2, \alpha_1 \in (-1, 1)\) and \( \tau \in \mathbb{R}_+ \).

To the best of the authors' knowledge, the first study in frequency-domain concerning the root location of scalar DDEs of retarded type goes back to the 30s and it concerns the Kalecki's dynamical model of an economic system [25]. Next, the complete characterization of the stability regions in the parametric space for the scalar DDE goes back to the 50s and the works of Hayes [26]. By the end of the 50s, Pinney [19] constructs the stability charts in the scalar and second-orded DDEs, covering both retarded and neutral cases. It should be mentioned that the first analysis in the second-order neutral and retarded cases can be found in the works of Callender et al. [27].

Regarding (6), note that the condition imposed to the parameter \( \alpha_1 \) corresponds to the stability of the trivial solution of the associated scalar delay-difference equation (in continuous-time), and it is known that its exponential stability is a necessary condition for the exponential stability of the null-solution of the DDEs of neutral type. For further discussions and explanations, we refer to [28, 8, 1], [4] and the references therein.
The corresponding characteristic function $\Delta : \mathbb{C} \times \mathbb{R}^2 \times (-1, 1) \times \mathbb{R}_+ \mapsto \mathbb{C}$ reads as:

$$\Delta(s; a_0, a_0, a_1, \tau) = s + a_0 + (a_1 s + a_0) e^{-\tau s}. \quad (7)$$

It is easy to observe that $\deg(\Delta) = 3$, and $\Delta$ reduces to a polynomial of degree 1 if $\tau = 0$. Thus, the cases of double, triple characteristic roots correspond to the only situations where we have over-order multiplicity. Such situations are specific to dynamical delay systems and have no natural meaning in the finite-dimensional case. Finally, it should be mentioned that the maximal multiplicity of the characteristic roots located on the imaginary axis out from the origin is equal to 1, and therefore such a root (if it exists) is simple.

**Remark 3.1.** It should be mentioned that, in the 60s, Wright [20] observed that the characteristic function $\Delta$ given by (7) can have three real roots but he has not explicitly analyzed the link between their multiplicity and the spectral abscissa. His argument was based on appropriate change of parameters and it did not exploit the degree of the corresponding quasipolynomial.

**Theorem 3.1** (over-order multiplicities). Consider the characteristic function $\Delta$ defined by (7).

1. **GMID [24]**: spectral value of maximal admissible multiplicity

   - The real $s_0$ is a root of maximal multiplicity 3 of $\Delta$ if, and only if, the coefficients $a_0, a_0, a_1$, the root $s_0$ and the delay $\tau$ satisfy the following relations
     $$a_0 = -s_0 - \frac{2}{\tau}, \quad a_0 = \left(-s_0 + \frac{2}{\tau}\right) e^{s_0 \tau}, \quad a_1 = e^{s_0 \tau}. \quad (8)$$

   - If relations (8) are satisfied then $s_0$ is necessarily a dominant root of $\Delta$.

2. **IMID : codimension 2**

   - The real number $s_0$ is a root of intermediate multiplicity 2 of $\Delta$ if, and only if, the following relations hold
     $$\alpha_0 = (\tau a_0 s_0 + \tau s_0^2 - a_0) e^{s_0 \tau}, \quad \alpha_1 = (-\tau a_0 - \tau s_0 - 1) e^{s_0 \tau}. \quad (9)$$

   - If the relations are satisfied and $\alpha_0$ satisfies the lower bound $\alpha_0 > 0$, then $s_0$ chosen such that
     $$-\alpha_0 - \frac{1}{\tau} \leq s_0 \leq -\alpha_0. \quad (10)$$

   is a dominant root of $\Delta$.

**Proof.** The proof follows the steps of an algorithm introduced in [29], and it consists of five steps: forcing multiplicity, normalization, appropriate (Fredholm) integral representation, explicit frequency bound estimation, and dominancy.

1. **Proof of Item 1:** it can be found in [24] and it is summarized as follows:

   (a) Forcing multiplicity: The real $s_0$ is a root of multiplicity 3 of $\Delta$ if, and only if, the coefficients $a_0, a_0, a_1$, the root $s_0$ and the delay $\tau$ satisfy the following relations
     $$a_0 = -s_0 - \frac{2}{\tau}, \quad a_0 = \left(-s_0 + \frac{2}{\tau}\right) e^{s_0 \tau}, \quad a_1 = e^{s_0 \tau}. \quad (11)$$

   (b) Normalization: Performing the translation and scaling of the spectrum by the following change of variables
     $$\tilde{\Delta}(z) = \tau (\Delta(z/\tau + s_0)) \quad (12)$$

     for $z \in \mathbb{C}$, we get the following normalized characteristic function $\tilde{\Delta} : \mathbb{C} \mapsto \mathbb{C}$,
     $$\tilde{\Delta}(z) = z + b_0 + (\beta_1 z + \beta_0) e^{-z} \quad (13)$$

   where
2. Proof of Item 2:

(d) Frequency bound: Assume that
\[ b_0 = \tau (a_0 + s_0), \quad \beta_0 = \tau (a_1 s_0 + a_0) e^{-\tau s_0}, \quad \beta_1 = a_1 e^{-\tau s_0}. \] (14)

It is easy to observe that \( \deg(\tilde{\Delta}) = \deg(\Delta) = 3. \)

(c) Integral representation: The real root \( s_0 \) is a root of multiplicity 3 of \( \Delta \) if, and only if, 0 is a triple root of \( \tilde{\Delta} \), that is:
\[ \tilde{\Delta}(0) = \tilde{\Delta}'(0) = \tilde{\Delta}''(0) = 0. \] (15)

The latter identities yield a linear system whose unique solution is \( (b_0, \beta_0, \beta_1) = (-2, 2, 1). \) From relations (14), one concludes that \( s_0 \) is a root of multiplicity 3 of \( \Delta \) if, and only if, relations (11) hold. Moreover, under the latter conditions, the quasipolynomial (7) reduces to
\[ \tilde{\Delta}(z) = \tilde{R}_0(z) + \tilde{P}_1(z) e^{-z}, \quad \tilde{R}_0(z) = z - 2 \quad \text{and} \quad \tilde{P}_1(z) = z + 2. \] (16)

Hence, the quasipolynomial \( \tilde{\Delta} \) admits the following Fredholm integral representation
\[ \tilde{\Delta}(z) = \int_0^1 q(t) \mathcal{X}(z,t) \, dt, \quad q(t) = t (1 - t) \quad \text{and} \quad \mathcal{X}(z,t) = z^3 e^{-zt} \] (17)
which is easily verified via an integration by parts.

(d) Frequency bound: Assume that \( z_0 = x_0 + i \omega_0 \in \mathbb{R}_+ + i \mathbb{R}_+ \) is a root of \( \tilde{\Delta} \), so that \( \tilde{\Delta}(z_0) = 0 \) if, and only if,
\[ |\tilde{R}_0(x_0 + i\omega_0)|^2 e^{2x_0} = |\tilde{P}_1(x_0 + i\omega_0)|^2. \] (18)

Considering a truncation of order 1 of the exponential term \( e^{2\tau} \), the latter is lower bounded by \( 1 + 2\tau \). Next, define
\[ F(x, \omega) = |\tilde{P}_1(x + i\omega)|^2 - (1 + 2\tau) |\tilde{R}_0(x + i\omega)|^2 \] (19)
where \( F > 0 \) for any \( x > 0 \). The zeros of \( F \) are characterized by the first-order polynomial
\[ G(\Omega = \omega^2) = -2 x \Omega - 2 x^3 + 8 x^2. \] (20)

The polynomial function \( G \) admits a single real root \( \Omega_0(x) = -x (x - 4) \), which reaches a maximum value at \( x^* = 2 \). As a consequence, \( \Omega_0 \) is bounded by \( \Omega^* = 4 < \pi^2 \). Thus, one obtains the desired frequency bound,
\[ 0 < \omega \leq 2 < \pi. \] (21)

(e) Dominancy: The goal of the frequency bound is to prove the dominancy by a contradiction argument. For this purpose, assume that there exists \( z_0 \in \mathbb{R}_+ + i \mathbb{R}_+ \) root of \( \tilde{\Delta} \). Then, the integral representation yields
\[ \int_0^1 t (1 - t) e^{-zt} \, dt = 0, \] (22)
the imaginary part of which is
\[ \int_0^1 t (1 - t) e^{-zt} \sin(\omega t) \, dt = 0. \] (23)

Now, the frequency bound \( 0 < \omega \leq \pi \) of the previous step entails that the function
\[ t \mapsto t (1 - t) e^{-\omega t} \sin(\omega t) \] (24)
is strictly positive in \((0, 1)\), thereby contradicting the last equality.
(a) Forcing multiplicity: The real number $x_0$ is a root of multiplicity $2$ of $\Delta$ if, and only if, the coefficients $a_0$, $a_1$, the root $s_0$ and the delay $\tau$ satisfy the relations below

$$a_0 = (\tau a_0 s_0 + \tau s_0^2 - a_0) e^{\tau s_0} \quad \text{and} \quad a_1 = (-\tau a_0 - \tau s_0 - 1) e^{\tau s_0}.$$  \hfill (\text{25})

(b) Normalization: Performing the translation and scaling of the spectrum by the following linear change of variables

$$\tilde{\Delta}(z) = \tau \Delta(z/\tau + s_0)$$  \hfill (\text{26})

for $z \in \mathbb{C}$, we get the following normalized characteristic function $\tilde{\Delta} : \mathbb{C} \mapsto \mathbb{C},$

$$\tilde{\Delta}(z) = ((-\rho - 1) z - \rho) e^{-z} + z + \rho,$$  \hfill (\text{27})

where $\rho = \tau (x_0 + a_0)$ is a real number.

(c) Integral representation: It can be verified via an integration by parts that the quasipolynomial $\tilde{\Delta}$ defined in (27) can be factorized as

$$\tilde{\Delta}(z) = z^2 \int_0^1 q_\rho(t) e^{-tz} dt$$  \hfill (\text{28})

where

$$q_\rho(t) = \rho t + 1.$$  \hfill (\text{29})

In our approach, the sign constancy of the polynomial $q_\rho$ for $t \in (0, 1)$ is necessary. We easily see that it is guaranteed if, and only if, $\rho \in [-1, +\infty].$

(d) Frequency bound: In the following, let $z_0 = x_0 + i\omega_0 \in \mathbb{R}^+ + i\mathbb{R}_+$ be a root of

$$\tilde{\Delta}(z) = R_0(z) + P_1(z) e^{-z}, \quad R_0(z) = z + \rho, \quad \text{and} \quad P_1(z) = (-\rho - 1) z - \rho,$$  \hfill (\text{30})

as defined in (27) and $z_0$ satisfies the following equality

$$|R_0(x_0 + i\omega_0)|^2 e^{2\omega_0} = |P_1(x_0 + i\omega_0)|^2.$$  \hfill (\text{31})

Considering a truncation of order $2$ of the exponential term $e^{z^2}$, the latter is lower bounded by $1 + 2x + 2x^2$ for any $x \in \mathbb{R}_+$, see [24, 29]. Next, we define the following function $F_\rho : \mathbb{R}_+^2 \mapsto \mathbb{R},$

$$F_\rho(x, \omega) = |P_1(x + i\omega)|^2 - |R_0(x + i\omega)|^2 (1 + 2x),$$  \hfill (\text{32})

which satisfies $F_\rho(x_0, \omega_0) > 0$. Moreover, the zeros of $F_\rho$ can be characterized by the following linear polynomial in $\Omega = \omega^2$

$$G_p(x, \Omega) = (\rho^2 - 2x^2 + 2\rho - 2x) \Omega - 2x^4 - 2(2\rho + 1)x^3 - (\rho (\rho + 2)x^2.$$  \hfill (\text{33})

In our analysis, we are interested in the cases where $G_p(x, \Omega)$ is bounded. Hence, let $\Omega_p^0(x) = N_p(x)/D_p(x)$ be the real solution of $G_p(x, \Omega)$, where

$$N_p(x) = x^2 (\rho^2 + 4\rho x + 2x^2 + 2\rho + 2x) \quad \text{and} \quad D_p(x) = \rho^2 - 2x^2 + 2\rho - 2x.$$  \hfill (\text{34})

We proceed by setting an upper bound for the solution $\Omega_p^0(x)$ with respect to the variation of the parameter $\rho$ in $(-1, +\infty)$. First, note that the denominator $D(x, \rho)$ admits for $\rho \in (-1 + \frac{\sqrt{2}}{2}, +\infty)$

$$x_0^2(\rho) = -\frac{1}{2} \pm \frac{\sqrt{2\rho^2 + 4\rho + 1}}{2}.$$  \hfill (\text{34})

Then, we divide our analysis into two parts.
i. \( \rho \in \left(-1, -1 + \frac{\sqrt{2}}{2}\right) \):

- The numerator \( N_\rho(x) \) admits 4 real roots:

\[
\begin{align*}
0, 0, x_N^\rho(\rho) = -\rho - \frac{1}{2} \pm \frac{\sqrt{2\rho^2 + 1}}{2},
\end{align*}
\]

where \( N_\rho(x) \) is negative for \( x \in (0, x_N^\rho(\rho)) \) and positive for \( x > x_N^\rho(\rho) \).

- The denominator keeps a constant (negative) sign, since it has no real roots.

Note that, since \( \Omega_0^\rho(x) \) is required to be positive, we only consider \( x \in (0, x_N^\rho(\rho)) \), case in which \( N_\rho(x) \) and \( D_\rho(x) \) are both of negative sign. Then, an upper bound for \( \Omega_0^\rho(x) \) requires lower bounds for both \( N_\rho(x) \) and \( D_\rho(x) \):

\[
\begin{align*}
N_\rho(x) &\geq -x^2 \left(-4x^2 + 2\sqrt{2} + 4x + 1\right)/2, \quad (36) \\
D_\rho(x) &\geq -1/2 - \sqrt{2} - 2x^2 - 2x, \quad (37)
\end{align*}
\]

which yields the following upper bound for the solution \( \Omega_0^\rho(x) \):

\[
\Omega_0^\rho(x) \leq \Omega^\gamma(x) = \frac{x^2 \left(-4x^2 + 2\sqrt{2} + 4x + 1\right)}{4x^2 + 2\sqrt{2} + 4x + 1}, \quad (38)
\]

which itself is bounded by \( \pi^2 \); see Figure 2-(a).

![Figure 2: (a) 3D plot showing how \( \Omega_0(x, \rho) \) (in blue) is upper bounded by \( \Omega_0^\gamma(x, \rho) \) (in green) for \( \rho \in \left(-1, -1 + \frac{\sqrt{2}}{2}\right) \) and \( x \in (0, x_N^\rho) \) (b) 3D plot showing how \( \Omega_0(x, \rho) \) (in blue) is upper bounded by \( \Omega_0^\gamma(x, \rho) \) (in green) for \( \rho \in \left(-1 + \frac{\sqrt{2}}{2}, 0\right) \) and \( x \in (0, x_N^\rho) \).](image)

ii. \( \rho \in \left(-1 + \frac{\sqrt{2}}{2}, 0\right) \): In this case, one can notice that \( x_N^\rho(\rho) < 0 \), which implies that \( D_\rho(x) < 0 \). Since \( \Omega_0^\rho(x) \) is required to be positive, we only consider \( x \in (0, x_N^\rho(\rho)) \). Using a similar analysis,
in order to set an upper bound for $\Omega^0_\rho(x)$, we first set a lower bound for both $N_\rho(x)$ and $D_\rho(x)$:

$$N_\rho(x) \geq x^2 \left(2x \sqrt{2} + 2x^2 + \sqrt{2} - 2x - 2\right),$$  \hspace{1cm} (39)

$$D_\rho(x) \geq -2 - 2x^2 + \sqrt{2} - 2x,$$  \hspace{1cm} (40)

which yields the following upper bound of the solution $\Omega^0_\rho(x)$:

$$\Omega^0_\rho(x) \leq \Omega^s(x) = \frac{x^2 \left(2x \sqrt{2} + 2x^2 + \sqrt{2} - 2x - 2\right)}{-2 - 2x^2 + \sqrt{2} - 2x}$$  \hspace{1cm} (41)

which itself is bounded by $\pi^2$; see Figure 2-(b).

Now, is the solution $\Omega^0_\rho(x)$ is upper bounded with respect to $\rho$ by the following parameter-free function

$$\Omega^s(x) = \begin{cases} 
    \frac{x^2 \left(-4x^2 + 2 \sqrt{2} + 4x + 1\right)}{4x^2 + 2 \sqrt{2} + 4x + 1} & \text{for } \rho \in \left(-1, -1 + \frac{\sqrt{2}}{2}\right) \text{ and } x \in (0, x^*_{\rho}(\rho)), \\
    \frac{x^2 \left(2x \sqrt{2} + 2x^2 + \sqrt{2} - 2x - 2\right)}{-2 - 2x^2 + \sqrt{2} - 2x} & \text{for } \rho \in \left(-1 + \frac{\sqrt{2}}{2}, 0\right) \text{ and } x \in (0, x^*_{\rho}(\rho)).
\end{cases}$$  \hspace{1cm} (42)

Hence, we have characterized the regions where the frequency is bounded.

(e) Dominancy: By a contradiction argument, assume that there exists $\omega_0 \in \mathbb{R}_+ + i\mathbb{R}_+$ root of $\Delta$. Then, the integral representation yields

$$\int_0^1 (\rho t + 1)e^{-\tau \omega_0} \, dt = 0,$$  \hspace{1cm} (43)

the imaginary part of which is $\int_0^1 t (\rho t + 1) e^{-\tau t} \sin(\omega t) \, dt = 0$. Now, the frequency bound $0 < \omega \leq \pi$ of the previous step entails that the function

$$t \mapsto t (\rho t + 1) e^{-\tau t} \sin(\omega t)$$  \hspace{1cm} (44)

is strictly positive in $(0, 1)$, thereby contradicting the last equality.

To conclude, if relations (25) are verified and $a_0$ satisfies the lower bound $a_0 > 0$, then the exponential decay $s_0$ is chosen such that

$$-a_0 - \frac{1}{\tau} \leq s_0 \leq -a_0$$  \hspace{1cm} (45)

is necessarily negative and dominant.

\[ \square \]

**Remark 3.2.** Note that in the over-order MID (IMID) case (item 2 of Theorem 3.1), one may expect to obtain a larger range to assign the dominant root albeit for truncation orders of the exponential term in the “frequency bound” step that are strictly greater than 2, as illustrated in Figure 3(b).

**Remark 3.3.** As pointed out in [12], the GMID does not allow any degree of freedom in allocating $s_0$. Indeed, if $a_0$ and $\tau$ are fixed then the assigned spectral abscissa is uniquely determined from (8) as $s_0 = -a_0 - \frac{1}{\tau}$. In order to allow some leeway in allocating, as illustrated in (45), one can relax the constraint by forcing the root $s_0$ to have an over-order multiplicity albeit lower than the maximal one. This fact is important from a robustness perspective.
Figure 3: (a) Spectrum distribution of the quasipolynomial function $\Delta(z)$ (b) With a truncation order of the exponential term raised to 4 the 3D plot illustrates how $\Omega_0(x,\rho)$ (in blue) is upper bounded by $\pi^2$ (in red) for $\rho \in (-1,1)$ and $x > 0$, which enlarges the assignment range.

To illustrate it, reconsider the motivating example, that is the feedback stabilization of a scalar conservation law with PI boundary control presented in section 2.1. Following (10), an assignable $s_0$ as a dominant double root of $\Delta$ has to satisfy

$$-\frac{\lambda}{L} \leq s_0 \leq 0,$$

which occurs if

$$k_i = -\frac{Ls_0^2}{\lambda} e^{\frac{L}{\lambda}}, \quad k_p = -\frac{\lambda + Ls_0}{\lambda} e^{\frac{L}{\lambda}}.$$

Remark 3.4. As emphasized in [12, 18], the over-order MID property has an interesting link with the well-known Kummer confluent hypergeometric functions. As a matter of fact, quasipolynomials with dominant roots of over-order multiplicities can be represented in terms of such special functions. As it was developed by E. Kummer, P. Humbert, E. T. Whittaker, F. Tricomi, L. Erdelyi and others, see, for instance, [30, 31, 32, 33], for every $a, b, z \in \mathbb{C}$ such that $\Re(b) > \Re(a) > 0$, Kummer functions admit the integral representation

$$\Phi(a, b, z) = \frac{\Gamma(b)}{\Gamma(a)\Gamma(b-a)} \int_0^1 e^{\lambda t^{a-1}}(1-t)^{b-a-1} dt. \quad \text{(46)}$$

In particular, the quasipolynomial (7) whose parameters satisfy (8), i.e. the GMID is satisfied, can be written as:

$$\Delta(s) = \frac{\tau^2}{6} (s-s_0)^3 \Phi(2,4,-\tau(s-s_0)).$$

However, the quasipolynomial (7) whose parameters satisfy (9) admits a double root at $s_0$ arbitrarily chosen in accordance with (10), i.e. the IMID is satisfied, can be written as a linear combination of two Kummer functions:

$$\Delta(s) = \tau (s-s_0)^2 \left( \frac{\tau (s_0 + a_0)}{2} \Phi(2,3,-\tau(s-s_0)) + \Phi(1,2,-\tau(s-s_0)) \right).$$

10
4. CONCLUSION

In this paper, we provided a complete characterization of the multiplicity-induced-dominancy (MID) property for single-delay linear first-order delay-differential equation (DDE) thanks to the five-step algorithm described in [24, 29]. Despite the complete characterization of the generic multiplicity-induced-dominancy (GMID) property for single-delay systems of arbitrary order [12], the intermediate multiplicity-induced-dominancy (IMID) property, which is more suited for control purposes, remains an open question. Further effort devoted to studying the distribution of zeros of Kummer’s confluent hypergeometric functions seems to be the key to answering this question.
